Elmira Reformatory, and it will continue to be so identified for better or worse. That the practical results obtained in this institution have been remarkable is generally conceded, but that the methods of discipline were not the most enlightened is also apparent. To misjudge a good system because of a bad feature, is neither fair nor wise, and is not our intention here. We freely concede that Mr. Brockway has done a great work, the evidence of which will long survive him; but he has also made a reputation as a flogger which will not quickly die. The law at Elmira seems to have required that a record be kept of all the floggings; and we sincerely hope that Mr. Brockway will not have to support by this record all his claims to immortality as a great penologist. The record is its own best commentary, for it shows a steady numerical progression of floggings from one year to another. The inference is that the culprits in Elmira were growing steadily worse, or that the habit of flogging was growing steadily on Mr. Brockway. We fear that both these inferences are correct, and we hope that this lamentable record will stand for all time as a warning to all disciplinarians. For ourselves we cannot quite disabuse our mind of a sense of want of confidence in an institution in which such a practice prevails. Flogging is a confession of weakness, and rebounds from the posteriors of the condemned upon the heads of the floggers. As a method of discipline it is subject to frightful abuse—a fact which we fear is demonstrated by the Elmira record. There is no more reason why it should be practised in a penitentiary or reformatory than in the army or navy, and we trust that in the case of Elmira it will now be superseded by something more decent, more rational and more humane.

The Relation of Leprosy and Smallpox.—United States Consul Plumacher, at Maracaibo, writes to the State Department a short note on the alleged curative action of the virus of smallpox on leprosy. Mr. Plumacher says that he had been informed by reliable persons in the Republic of Colombia that patients afflicted with leprosy have been cured of this disease by an attack of smallpox. In the State of Santander, he alleges, one-fifth of the population have in them the germs of leprosy, and in the same State smallpox is spreading rapidly. An examination of the records of the lepers of Maracaibo revealed the fact that none of these patients had been vaccinated in former days before being attacked by leprosy. Mr. Plumacher, on this very scanty evidence, thinks that there may be "some connection" between the two diseases, and by this term he evidently means to suggest that the virus of smallpox may be inimical to the bacillus of leprosy. He would like to see this question solved by competent investigators. From his own personal observation he thinks that but few lepers in China and in Asia generally have been vaccinated.

We agree with the consul that it might be a good thing to test this question, for the incompatibility of one disease with another is sometimes a problem of interest and importance. There is nothing inherently improbable in the mutual antagonism of two infecting microbes. The struggle for existence in nature is a widespread and ferocious one, and takes place on many diverse fields. It may occur on a microscopic scale. So far as smallpox and leprosy are concerned, the subject seems thus far to be merely speculative. Mr. Plumacher's statement that one-fifth of the population of Santander have leprosy is unsupported by any evidence in his letter; and the mere fact that any number of lepers have not been vaccinated is no proof that if they had been vaccinated they would not have had leprosy. Such loose logic will not serve in pathology.

General Otis on Measles.—Like most commanding officers, General Otis evidently believes that soldiers are intended for fighting and not for lying sick in the hospitals. This would be an admirable theory in time of war if the facts only supported it; but facts are stubborn things, and soldiers will persist in getting sick, even in defiance of major-generals. In *Harper's Weekly* for August 4 Mr. William Dinwiddie contributes a bright sketch of the military hospitals in Manila, and incidentally throws some side lights on General Otis as a diagnostician and a sanitarian. On board the transport en route for Manila two soldiers fell ill with measles (a grave disease in military life), and the young assistant surgeon asked to have them put on shore at Honolulu in the Sandwich Islands. When the cases were reported to the commanding general, who was also a passenger, he exclaimed "Nonsense! Let me see the men." Being shown the patients he proclaimed that the disease was not measles, and ordered them kept on board. At this the young surgeon stated bluntly that he had made a diagnosis of measles, but that if General Otis would give him an official statement that the disease was not measles, he saw no reason why the men should be put ashore. Whereupon General Otis saw the point, and ordered the men to be taken off the ship.

In Manila General Otis rigged up an old Spanish hospital that was indescribably unsanitary, and crowded 1400 patients into it. This institution was called by the military surgeons "Otis's hospital," and Mr. Dinwiddie says that the general seriously handicapped its organization and administration. When 12 men were reported insane, the general, probably not wanting "to alarm the public at home" (a chronic fear of his), ordered that only half the number should be sent back to the United States, and that the first six in alphabetical order should be chosen! This surpasses Sancho Panza. When the hospitals got too full, the general declared that half the inmates were only shamming, and sent a staff officer to investigate and weed them out. As the staff officer presumably took his medical educa-

cation at West Point, it is evident what a valuable assistant diagnostician he must have been. But all medical affairs are not thus in Manila, and Mr. Dinwiddie describes several military hospitals, notably the Second Reserve Hospital, under Major F. R. Keffer, that are models.

The Thanks Given to Health Officers.—No more striking example of public ignorance of and indifference to the prevention of disease can be cited than the abuse so often bestowed upon sanitary officers who perform their duties properly. The local commercial interests so often temporarily interfered with by the activities of a conscientious officer have much to do with shaping expressions of sentiment. Newspaper editors and writers, usually devoid both of knowledge of sanitation or desire for the enforcement of good laws do much towards spreading dissatisfaction based upon falsehood. In the city of San Francisco we have had a very good illustration of the pernicious activity of banal commercialism and interested newspaper influence. Self-sacrificing health-officers who have braved personal danger of the gravest nature and performed most disagreeable duties under the imminent danger of death to themselves, have been vilified, slandered, and threatened. Heroism, because in the cause of science and humanity, has not only gone without recognition, but has brought fierce hatred upon the men who have shown it. This flagrant illustration of the spirit of the press and people is not an isolated one. From earliest history there have been many instances of the same kind. In Venice during the sixteenth century the officers corresponding to our sanitary officers are said to have been killed by the mob, under the impression that they were disseminating the disease. Hardly a metropolis of the world has been devoid of instances of mob violence towards health-officers engaged in suppressing small-pox. In a small western village last year the medical health-officer was shot down because he quarantined a case of scarlet fever.

There should be some way of opposing or lessening the unthankful and unappreciative spirit that such instances show to be so widespread. Plainly, the majority of persons who hold such views hold them because of ignorance. In some instances,—and these are especially regrettable,—they hold them because some physicians, not in sympathy with modern sanitary methods, encourage their clients to resist the health-officers. This form of opposition, however, usually expends itself in suits for damages rather than by resorting to personal injury. Both forms of opposition are reprehensible. What should be done is to appeal to the intelligence of the people in the effort to secure their cooperation. Explain every measure and show its reasonableness; appeal to the feeling of good citizenship; be patient and painstaking in explanation; today, tomorrow, and the day after, if necessary, repeat the

explanations, patiently and goodnaturedly. This is the kind of a policy that will enable the health-officer to secure the confidence and the appreciation of the people in the end. As for the doctor who finds the greatest outlet for his superfluous energy in opposing the health-office and instigating others to the performance of disagreeable acts, simply get him on record in the journals and societies as the advocate of his peculiar views,—the genuine sentiment of his professional brethren will do the rest.

The Alcohol Question Again.—During the past year much attention has been given to the question of the effects of alcohol on the system, as a result chiefly of Professor Atwater's calorimeter experiments and the controversies regarding the army canteen. Professor Atwater's conclusions have been favorably and unfavorably criticised by both medical and lay writers. His latest critic is Professor W. S. Hall, of Northwestern University (*Journal of the American Medical Association*, July 14, 1900). Among other matters Hall calls attention to the following facts with regard to alcohol as compared with foods. More and more of it is required to produce the same effect, which is not the case with real foods; when used habitually it causes an uncontrollable desire for more; it is likely to produce serious derangement of the central nervous system; it is a product of decomposition and excretion and in common with all excretions is poisonous; its use is followed by an accumulation of fat, by decrease in activity of muscle-cells and brain-cells, and the brain-action is less accurate after its use. Most of these criticisms are quite correct and deserve the attention of physicians who are in the habit of prescribing alcohol freely for their patients.

It appears, however, that Professor Atwater has been incorrectly reported by many of his critics and many of his conclusions have been misrepresented. In an address recently delivered before the National Educational Association and published in the *Educational Review* Professor Atwater takes occasion to correct some of the misapprehensions and misstatements of his critics. He considers that alcohol in small quantities is in a sense a food, but in large quantities always a poison. He has rarely if ever heard alcohol spoken of as a poison by any specialists of recognized position. Alcohol does not build tissue, is not stored in the body for future use, but it is oxidized and does yield energy and may be called a partial food when taken in moderate quantities and cannot then be properly called a poison. As to the injurious effects of large quantities no difference of opinion can exist. Professor Atwater specially calls attention to the current methods of teaching with regard to alcohol in the schools. He believes that what should be taught is that alcohol is not a food in the sense in which that word is ordinarily understood, that the moderate use of alcohol is dangerous; but if in-

telligent children are told that alcohol in the form of light wines and beer is a poison they know or will know that they are misled. It is wrong to teach that alcohol in small quantities is always necessarily harmful and it is false to teach that scientific observations have demonstrated any such conclusion. A great obstacle to temperance reform is the exaggeration and false statement which often makes so great a part of the means used to promote such reform. "Is not temperance advisable even in the teaching of temperance doctrine?" he asks. We regard Professor Atwater's review of the entire subject an admirable argument in favor of temperance in the highest sense. Reform is seldom promoted by misstatement of extremists, and rational people, whether children or adults, are more strongly influenced in the long run by careful adherence to the truth. If his address could be used as a substitute for the official doctrine which is taught in many schools no doubt the cause of temperance would be promoted as well as that of science.

Further Light Upon the Relationship of Epilepsy and Rickets.—As a result of the investigations into the pathology of epilepsy which have been in progress during the last three years in the laboratory of the Ohio Hospital for Epileptics, particular prominence has been given to the coexistence of the lymphatic constitution and idiopathic grand mal. In a careful anatomic analysis of 100 cases this point has been verified. The lymphatic constitution is especially determined by the prolonged existence of a lymphoid thymus, by general lymphadenoid hyperplasia as shown in the regional lymph-glands and by the follicles of the spleen and intestines, by narrowed arteries, sometimes with evidences of old rickety osseous deformity. These conditions are, of course, to be sought in suitable cases before advanced growth-changes, wasting from pronounced debility or from the ravages of other diseases have eradicated them. Young adults, victims of idiopathic grand mal, dying suddenly in ordinary health, as these epileptics often do, are particularly favorable subjects for this demonstration, though the conditions are exaggerated in children.

Granting this concurrence of lymphatism and grand mal, what deductions may be made? Possibly it is merely coincidence, though one naturally looks further. Proceeding in this way it was found that certain neuroses of infancy and childhood, notably laryngismus stridulus, tetany, and teething convulsions, had been shown to be accompanied by the lymphatic constitution. These neuroses had long been suspected by clinicians as standing in some relationship to epilepsy; and were further supposed to be the results of that serious constitutional discord of infants, rickets. Lymphatism is also regarded as a rachitic adenopathy. Thus these studies were finally directed to rickets as a factor of apparently great importance in the pathogenesis of

epilepsy, and these conclusions find expression in Ohlmacher's papers.

From the clinical side similar inference had been reached, particularly by Gowers, who, from an analysis of the previous histories of epileptics, was strongly impressed with the influence of rickets in the production of epilepsy. The way, therefore, now seems opened both from clinical and pathologic investigations to place in one category whose anatomic basis is that form of rachitic disturbance known as the lymphatic constitution the spasmodic neuroses of infancy (laryngismus, tetany, teething fits, and possibly others) and the idiopathic grand mal of later life. This seems to mark a distinct advance in our knowledge of these affections, though much still remains to be done. What is the real nature of rickets, whose already sinister significance is magnified by these discoveries? A recent view and one which is gaining ground is that rickets is primarily an infection, and in this light epilepsy may be looked upon as the remote consequence of a peculiar microbic affection.

But while these important questions must remain for patient pathologic research to unravel we may profitably recall the well-established clinical fact that dietary and hygienic errors are potent, if not essential factors in preparing the way for rickets, and thus, while we are practically helpless as to the treatment of epilepsy once established, may we not reasonably expect to prevent this dreadful disease by adopting the measures of correct infant feeding and infant care which modern pediatrics has emphasized in the prevention or treatment of rickets? This practical conclusion is foreshadowed by Gowers, and independently reached by Ohlmacher.

A Simulated Abnormality.—An aged colored individual is making the rounds of the physicians' offices and hospitals, exhibiting himself as a man with two hearts. He also claims to be able to displace his hearts into the abdominal cavity. He has traveled widely in this country and has been in Europe. There is no evidence whatever that the man has two hearts, nor is there any sign that an aneurysm exists. When he is about to "dislocate his heart" he asks the examiner first to listen with the stethoscope or phonendoscope over the normal cardiac area for the heart-sounds. He then twists and contorts himself in various ways, using actively the muscles of the anterior abdominal wall. As he does this there is seen to rise suddenly in the left iliac region a rounded, pear-shaped prominence, which is pulsatile and to which he now asks the examiner to apply the stethoscope. An obscure rhythmic sound is heard over the area which is the size of a large fist, and which conveys to the palpating hand a sensation of throbbing. He can produce a similar swelling, though less prominent, on the right side. With a great show of effort he holds the prominence on one or the

other side for about 20 seconds. If the examiner, instead of listening over the supposed heart, places his stethoscope in the normal situation of the valve-points, he readily detects the heart sounds in practically undiminished intensity. Moreover, percussion over the supposed hearts gives a more or less tympanitic note. The man has evidently by long practice gained a peculiar control over the superficial abdominal muscles—such as some persons have over the scalp and ears—by means of which he is able to throw a certain section into prominence and to produce a rhythmic vibration that closely simulates, both in character and rate, the pulsation of the heart.

Correspondence.

EPILEPSY WITH LUXATION OF JAW.

ALFRED FRIEDLANDER, M.D.,
of Cincinnati.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE report of two cases of epilepsy with luxation of the jaw, in the JOURNAL for July 14, leads me to report the following additional case: D. M., aged 72, an inmate of the Home for the Jewish Aged and Infirm, of this city, has had attacks of epilepsy for many years. Three years ago, after an attack, it was noticed that there was a complete luxation of the jaw. Since that time this accident has happened frequently, and in the past 15 months there have been 15 epileptic attacks, with luxation of the jaw each time. The reduction has always been accomplished without any difficulty. There has been no luxation at any time excepting during the epileptic seizure.

PSEUDOMENSTRUATION.

By M. CHERTLER, M.D.,
of New York.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I NOTICED in JOURNAL of July 7 a second case of precocious menstruation, or, rather, called pseudomenstruation, reported by Dr. Wales of Chicago. I have under observation 2 cases which are of a similar nature. The first case is in the tenth child of a tuberculous woman, who passed through a normal. On the third day of the puerperium the attending nurse drew my attention to the genitals of the infant being bloody. I carefully separated the labia and fully convinced myself that there was no external injury to the parts, and that the discharge was vaginal, of a sero-bloody character. It increased in quantity on the fourth day, and ceased totally on the eighth day. There was no recurrence of the discharge within 10 months while under my observation. The second case was in the fifth child of a healthy mother. The discharge was noticed first on the third day and ceased on the ninth day, without recurring again within 6 months under observation.

The features of interest in these cases are that both mothers were of blond type and multiparas, and one mentioned of having heard her mother say that she was also

bleeding when born, a fact which I omitted to mention when describing the first case. In a discussion on purpura hæmorrhagica, held at the Eastern Medical Society of New York, I brought the attention of the society to the 2 cases, and some very eminent practitioners were of the opinion to classify these cases in the same category with purpura. Text-books and literature mention very little on the subject.

MEDICAL MISSIONARIES' EDUCATION.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

IN the PHILADELPHIA MEDICAL JOURNAL of April 7, 1900, on page 780, under the heading Medical Missionaries, is the following: "We would like to know of the fact if any medical college has ever offered free tuition or free post-graduate courses to those of our brethren who have devoted their lives to carrying the gospel of scientific therapeutics to the peoples cursed with the horrors of the medicine of barbarism."

We beg to reply to the above by saying that the Laura Memorial Woman's Medical College, located in Cincinnati, Ohio, has given, and we believe continues to give, free tuition to those intending to engage in medical missionary work in foreign countries. At present one such member of its Alumni is in China, another in Manila, and a third in Korea, all engaged in medical work.

We are most grateful for the kind words, in editorial comment, in regard to medical work in the East. Its difficulties and its great need will become the better appreciated as it becomes the better known.

EMMA ERUSBERGER, M.D.

Seoul, Korea, June 4, 1900.

FACIES OF PHTHISIS.

By ALBERT S. ASHMEAD, M.D.,
of New York.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE characteristics of the "infrasuorbital" region mentioned by Dr. Eadie, in the JOURNAL, July 14, whose absence he thinks would indicate predisposition to consumption, (non-resistance to the attack of years), in my opinion are certain signs of longevity. They are notably present in all the members of my mother's Jewish-Holland ancestry, especially the women of her race. Without exception these women have lived to a great old age, some of them over a hundred years. My mother lives at 77; her mother died at 93; her grandmother died at 93. Her grandmother's brother, died at 107. My mother's mother's sister lived to be 88. My mother's sister died at 89. My maternal great aunt died at 93, etc. All these women had that peculiar facial characteristic. They were money-makers; their husbands were rich; *the brain of the wives made the money*. This money-sense belongs to the family. Other mental characteristics of these people were cruel persistence, unswerving purpose, obstinacy even to the point of *brutality*; *moral, mental, and physical endurance*. They reasoned from the standpoint of an eye for an eye, and a tooth for a tooth. If any one did them a wrong, they would never forgive it. They bided their time, and stabbed back—a characteristic typical of longevity (unless the other fellow has a shotgun). However, these traits are not so well developed in the males of the race.

Carcinoma is rife in this blood, and so also is insanity.

TREATMENT OF LUPUS BY THE CONCENTRATED LIGHT-RAYS.

By HENRY W. STELWAGON, M.D.,
of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

YOUR readers may be interested in knowing of the active work going on in Prof. Finsen's Institute in the treatment of that most rebellious and progressive cutaneous disease, lupus vulgaris. The method is now pretty generally known, the writings of Prof. Finsen, Dr. Bangs, and later of Dr. Bie, all of Copenhagen, having given the details and the brilliant results of this plan of treatment. It has now been practised for several years, and the gentlemen above and Drs. Forchheimer, Larsen, Sunding-Smith, and Balee, all associated with the Finsen Institute, are even more enthusiastic today than in the first year of its introduction. Their earnestness and enthusiasm must impress every medical visitor, as it did me, and indicate very positively that it is not its novelty that is attracting patients, but actual worth.

The Institute at present consists of several unpretentious small one-story buildings, used variously for laboratory, reception-room, room for treatment of the mucous membranes, and two for the light-treatment itself, and tables and stands for sun-condensers outside for the sunlight-treatment. In the latter are 5 strong arc-lights of 60 to 80 amperes. From each of these run four tubes containing the light-condensor and which are directed upon the part to be treated. These arc-lights are used in cloudy and rainy weather and during the cold winter days. The first two days I spent at the Institute it was rainy, and the treatment was carried on under these arc-lights. There were four operating tables about each lamp, on each of which lay a patient, making 20 patients under treatment at one time. At each table was a nurse, whose duty it is to press a hollow disk of glass on the spot previously marked out by an assistant, and through which the light is directed. Through the disk constantly circulates cool water to prevent severe burning action of the light-rays. This is kept pressed down firmly so as to push out the blood in the part and thus favor deeper penetration of the light. The light shines so brilliantly on the spot that nothing can be seen by the naked eye except a white dazzling area, so that in order to be able to inspect it satisfactorily and also to protect the eyes from the constant exposure to the light, the nurses wear very heavy dark glasses. The medical assistants pass around from time to time to see that the treatment is being given properly. One hour and a quarter is allotted to each set of 20 patients—one hour for treatment and the extra quarter for time necessary in changing the patients, adjusting the rays, etc. On days when the sun is shining, as it was on the third day of my visit, the treatment is carried on out of doors, and the arc-lights are temporarily dispensed with. The nurses become somewhat deeply bronzed from the sun exposure. From conversation with assistants the conclusion seems to be that upon the whole the arc-light is preferable. It is stronger in action and therefore the immediate reaction is sharper than by the sunlight-treatment. The various patients with whom I talked agreed with this.

The number of lupus cases here for treatment seems legion. The operating tables are occupied from half-past seven in the morning till nine in the evening, with the exception of one to two hours in the afternoon for rest of the assistants, nurses, etc. From seven patients treated the first year—1897—the clientele has grown beyond management. There are

now over 100 on the waiting-list. These patients are from all parts of the world, the larger portion being, of course, from Denmark. There are many from Germany, and a number from Austria, England, Scotland, and France; and I was informed by Prof. Finsen that he had had a few from our own country.

The cases varied in extent from slight to the most extensive types. Many had been treated by other methods, but unsuccessfully, or with only temporary success. The patients themselves seem enthusiastic, and come daily with unvarying regularity. The interest of the nation and city has been aroused, the government having contributed a quarter million kronen toward the erection and equipment of a commodious building. A private citizen has volunteered to pay the expenses of taking 14 of the cured patients to the International Dermatological Congress at Paris the coming August.

Among the skin-diseases observed here among the Danes, lupus would seem to form a good proportion; but Prof. Finsen informed me that this was not striking before the institution of this treatment here, since which time the cases have flocked here from all parts of the kingdom. A point that struck me forcibly is the large percentage of cases in which the mucous membranes—of nose or mouth—are involved. In these cases, while the skin-lesions are treated with the rays, the mucous membranes are necessarily otherwise managed. An application of a strong iodine solution is made daily, and twice weekly a galvano-cauterization is done.

The treatment seems successful. I saw several cured cases and many undergoing steady improvement. Recurrences seem rare so far, and readily managed. The patients are photographed before beginning treatment, and once or twice during the period of treatment, and when cured. The great disadvantage is the time necessary, and expense, and the constant attention and assistance in carrying out the treatment. In slight cases a few months at the most will suffice, but in extensive cases it extends beyond a year. I saw and conversed with a few patients, in whom this lupus involved the whole face and neck, who had had a daily sitting for more than a year, but even these were satisfied with the progress.

The treatment is paid for by patient or State—each patient from Denmark paying about \$18 monthly, and each patient from outside of the country about \$30 per month. The patients board themselves outside of the Institution—for the most part in two pensions especially established by two patients previously treated and cured. Rich and poor are treated in the same place and under like conditions.

In concluding, I take pleasure in stating that Prof. Finsen and his assistants extended me every courtesy for thoroughly inspecting the apparatus and the details of carrying out the method, afforded opportunity of seeing cured cases, and permitted free questioning of the attendants and the patients under treatment.

Spindle-celled Sarcoma of the Superior Maxillary.—C. A. Hamann (*Cleveland Journal of Medicine*, July, 1900) reports the case of a girl about 10 years old with a growth of the superior maxillary bone apparently starting in the antrum. The entire superior maxillary bone, part of the malar bone of the right side, and the floor of the orbit were removed, care being taken to preserve the orbital periosteum as a support for the eyeball. Recovery was uneventful and histologic examination showed the neoplasm to be a small spindle-celled sarcoma. It has been 2½ years since operation and there has been no recurrence. [M.B.T.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

The New Jersey Sewerage Commission served notice on the city of Plainfield that its sewage-disposal beds must be at once overhauled and improved or else proceedings would be instituted. The chief complaints come from the neighboring town of Dunellen.

Typhoid in Johnstown.—An epidemic of typhoid fever has recently visited Johnstown. Cambria Steel Company employes to the number of 150 are off duty on account of illness, about half of whom are suffering from that disease. One physician reports 16 cases. No particular cause has yet been assigned, for the water is in good condition.

Dr. Atkinson Injured.—While visiting the Mt. Gretna camp, Dr. William B. Atkinson, of the Pennsylvania State Board of Health, was thrown from a carriage and had his head badly cut and his hip crushed. He is now at his home in Philadelphia, in a serious condition. He had gone to the camp to make an official report of its sanitary condition.

Pure Water for Public Schools.—Some time ago \$35,000 was appropriated by the Councils of Philadelphia to furnish filters for use in public schools of the city. These filters have been referred to the Bureau of Health for a bacteriologic examination. The ordinance directs that no chemicals of any kind may be used and that each filter must have a capacity of removing 95% of bacteria.

Sanatorium for Fairmount Park.—Permission has been granted by the Park Commission of Philadelphia to a morning newspaper to establish a sanatorium in the Lippman mansion on the Wissahickon Drive. It is purposed to maintain there a temporary home during the summer months for anemic and debilitated small girls. The building will be thoroughly renovated and equipped and provided with nurses and caretakers.

Typhoid in Pittsburg.—Pittsburg is afflicted with an epidemic of typhoid fever, for which the sanitary authorities are unable to account. Some attribute it to impure water, but the ordinarily healthiest sections of the city are affected while the slums are free from the disease. When the matter is thoroughly investigated something else will possibly be found to be the potent cause. The epidemic in case the water-supply is at fault should be most virulent in those parts of the city where the filth-conditions are most favorable to its spread.

The Sanitarium Association of Philadelphia.—The Sanitarium Association of Philadelphia has now reached the 24th year of its active work, having opened for the present season on June 7. The admissions from that date to the present time were 115,652, being an average of 2,628 daily, and comprised 15,891 adults, 13,128 infants, and children over 2 years, 86,633. Of bathers there were 14,654 boys, 16,446 girls, and 2,466 infants. Admitted to the hospital, 61 sick small children with mothers. The increase of admissions over last year was 16,846. The largest on any single day was 5,157 on July 7.

Pennsylvania Hospital.—The one hundred and forty-ninth annual report of the Pennsylvania Hospital recently issued shows that during the past year 35,195 patients were treated. The hospital ambulance service answered 1,401 calls, and police patrol wagons brought 1,676 cases to the institution. The total income of the hospital from all sources was \$754,464.69; expenditures, \$655,409.34, leaving a balance of \$99,055.35. To feed patients during the year it was necessary to provide, among other food-supplies, 113,945 pounds of meat, 22,267 pounds of poultry, 12,142 dozen eggs, 12,155 pounds of butter, 58,668 pounds of bread, and 149,256 quarts of milk.

Paving Concerns a Menace to Health.—On July 18 the Philadelphia Board of Health, at a special meeting, received the reports of Chief Nuisance Inspector Kennedy and Chief Medical Inspector Taylor, in which it was stated that the plants of the Alcatraz Paving Company and the

Richardson and Ross Company were a nuisance and that the dust that emanated from the plants were injurious to health. In accordance with those reports the Board adopted a resolution in which the companies were allowed 20 days from the date of service to abate the nuisance, and on the failure of the companies to comply the Health Officer was authorized to close the works."

A Leaky Reservoir.—The north basin at the East Park reservoir, Philadelphia, has only 3 feet of water in it. The Water Bureau has drained 2 feet of water from the basin and allowed it to run into the river. A patch of the brick lining of the north embankment 15 feet square has been removed, but a repair of the troublesome leak has not yet been effected. Among the residents in the vicinity fear of inundation has given place to dread of offensive effluvia should all the water be drained off, exposing the settlements of years and thousands of fish which now alive, could not be expected to live in the mud. It is intended to keep a few feet of water in the reservoir while work is prosecuted, following up the line of the leak.

Vital Statistics of Philadelphia for the week ended August 11, 1900:

Disease.	Cases.	Deaths.
Total mortality		452
Inflammation of appendix 5, bladder 2, brain 11, bronchi 1, kidneys 11, heart 1, lungs 12, peritoneum 3, pleura 1, stomach and bowels 34		81
Lungs—tuberculosis of 56, congestion of 1, edema of 2, hemorrhage from 1, abscess of 2		62
Marasmus 23, inanition 19, debility 9		56
Cholera infantum 47, morbus 1		43
Heart—disease of 30, fatty degeneration of 3		33
Carcinoma of breast 2, liver 7, rectum 1, stomach 5, uterus 5, sarcoma of breast 1, tumor of brain 1		22
Old age		21
Apoplexy 12, paralysis 4		16
Casualties		15
Convulsions 13, puerperal 1		14
Bright's disease 6, uremia 6, diabetes 2		14
Brain—abscess of 1, congestion of 4, disease of 1, hemorrhage from 1, softening of 3, dropsy of 1		11
Diphtheria	46	7
Septicemia		4
Suicide—drowning 1, laudanum 1, hanging 2		4
Cirrhosis of liver		4
Stroke		3
Dysentery		3
Whooping-cough		3
Burns and scalds		3

NEW YORK.

Poisoned by Ice Cream.—At Reading Center, N. Y., 18 persons were poisoned recently by eating ice-cream. All will recover, but 12 were made violently ill.

The Geneva City Hospital will receive \$10,000 by the will of the late Judge Francis O. Mason. Upon the death of 2 sisters of the deceased, it will also receive \$80,000 additional.

The Boston Wage Earners' Emergency Hospital recently received an automobile ambulance from Philadelphia, the first vehicle of the kind built there. Only one other is known to be in service and that is in New York City.

To Improve Ellis Island.—Bids were opened at the Treasury Department, August 7, for the construction of surgeons' house, hospital outbuildings, ferry house, and covered way for the United States Emigration Station at Ellis Island, New York.

Addition to St. Catherine's Hospital.—A new wing for the care of tuberculous patients is about to be erected to St. Catherine's Hospital, in Williamsburg, Brooklyn. The estimated cost is \$30,000, and of this \$18,000 has already been raised by the hospital society.

Yellow Fever in New York.—Health Officer Doty, of New York, gave out a report concerning a patient at the Swinburne Island Hospital, who was removed from the Spanish steamer *Montserrat*, which arrived recently from Havana. Since then it has been discovered that he has yellow fever of a very mild type.

New Infant Asylum Building.—The Board of Managers of the New York Infant Asylum filed plans recently for a four-story brick asylum building, estimated to cost \$100,000, to be erected at Amsterdam avenue and Sixty-first street. The building will be constructed with a view to adding three stories in the near future.

The Board of General Appraisers in New York has decided that dried lizards are dutiable as a medicinal preparation and not as unenumerated merchandise. They are boiled in water very much after the manner of preparing herbs and similar articles. The resultant concoction is used as a drink to impart strength and vigor to the taker.

Plague and Immigration.—Health Officer Doty, of New York, cabled to the United States Consul at Hamburg for particulars in regard to plague at that port, from which large numbers of emigrants embark to this country. The following is his reply: "Merely suspicious; 1 sporadic case, sailor, South American, entirely isolated. Progress satisfactory, steamer quarantined, no danger." Later news announce the death of the patient.

Sore Eyes Caused by Public Bath House.—Many persons who have been using the free public bath on Bridge Street, Brooklyn, have suffered from a curious affection of the eye. Many of the cases have been treated at the Eye and Ear Infirmary. Some think a sewer which empties into the river near the bath-house may be responsible, while others think the steam-laundered towels may be the cause of the condition. An investigation will be made by the infirmary's physician.

Bellevue Dispensary.—The doctors and attendants of Bellevue Dispensary, New York, have been taxed to their utmost to care for the heat victims. During 4 days of the recent hot spell there has been an average of 61 children patients, suffering with disorders caused by the heat. The Outdoor Poor Department has received an average of 25 applications a day from mothers to have their children taken to Randall's Island. About 500 men and women have applied daily for treatment.

New Maternity Hospital.—The Bellevue University Building of New York, now used by the Cornell Medical College, has been converted into a maternity hospital, doing away with the old maternity hospital at Bellevue Hospital. There will be a dispensary on the ground floor, a maternity hospital on the first and second floors, and a dormitory for the Bellevue Hospital servants on the top floor. The Cornell Medical College will move into its new building soon, and the change will then be made.

NEW ENGLAND.

Divine Healer Got 32,000 Letters.—Postmaster Hibbard of Boston announces that the last piece of mail directed to Francis Truth, the "Divine Healer," has been sent back to the writers. The total number of letters was 32,000.

A Strange Medical Case.—Miss Hattie Stone, of Danbury, Conn., at present lies at her home in a precarious condition. Recently she began to sneeze violently and soon found that she could not stop. A physician was sent for and when he arrived she was weak and exhausted. The physician adopted heroic measures and the convulsions ceased suddenly. Twice the sneezes have returned, and each time the physicians have checked them, but they say that an unusually severe recurrence may result fatally. A nervous disorder is said to be the cause of the trouble.

CHICAGO AND WESTERN STATES.

The "Zion" leader, John A. Dowie, has started on a tour of the Old World.

Anthrax on a California Ranch.—Anthrax has broken out on the Tittmore ranch, 7 miles from Sacramento. Many cattle and several horses have died. Diagnosis is confirmed by microscopic examination.

Poisoned by Drug-store Soda.—Several people in Indianapolis have been poisoned by eating ice-cream served in soda water at some drug stores. No deaths have been reported, but several people have been made seriously ill.

St. Louis Marine Hospital.—Bids for the construction of the isolation ward and disinfecting annex to the United States Marine Hospital at St. Louis were opened recently. The lowest bid was for \$2,691, the work to be finished in 3 months.

Italian Smallpox Patients Released.—The eight Italians who were quarantined in an emigrant car near Adair, I. T., have been released. The railroad company took care of the smallpox patients, and when released from quarantine took them away as quickly as possible.

Smallpox in Illinois.—Dr. Charles B. Johnson, chairman of the State Board of Health, was called to Charleston, Ill., to examine the cases which have been designated as "Cuban itch." He pronounced them smallpox in a mild form. The chairman of the local Board of Health disagrees with this diagnosis.

Child-Labor.—Through the efforts of Factory-Inspector Williams, of Milwaukee, 25 boys have been discharged from the work of serving beer in the parks. The Wisconsin State law prohibits the employment of youths under 14 years of age, and also prohibits the employment of youths under 16 after 9 o'clock in the evening.

Milk Condemned in Milwaukee.—State Food and Dairy Commissioner Adams and members of his staff are in Milwaukee on a tour of inspection, particularly of the milk shipped into the city. Several cans of milk were dumped into the lake, the officials having good reason to believe that the milk came from cattle affected with tuberculosis.

Water of Lake Michigan Remains Cool.—Dr. Bennett, of the health department, went out on Lake Michigan recently to take samples of the water and to find its temperature. He found the temperature of the water at the intake tunnel was 46° F. Three-quarters of a mile from the shore the water near the surface showed a temperature of 56°.

Poultry Condemned by Chicago Health Department.—The Health Department of Chicago recently condemned 75,000 pounds of poultry, which was shipped there from St. Paul, having passed through a fire in a cold storage warehouse in that city. From the same fire \$60,000 worth of salmon was also expected, but the Chicago Health Department was notified that it had been sent to Des Moines.

The Health of Milwaukee.—The Associated Charities of Milwaukee report that there have been few cases of sickness among the poor in that city during the hot weather, while the health department records show an unusually light percentage of infant mortality. The crusade against dishonest milk dealers, which was conducted not long ago, is yielding good results, as is also the excellent quality of the water-supply.

Baking-powder Case.—What is known as the "baking-powder case" of Jefferson, Mo., has reached the Supreme Court. The style of the case is *State of Missouri vs. Whitney Layton*. Layton was convicted March 31, 1900, of manufacturing and selling "Health Food," a baking-powder which is alleged to contain alum, and he was fined \$100. The object of this appeal is to test the constitutionality of the pure food law enacted by the last Legislature. Should the docket fee be paid by the first day of September the case will be docketed for hearing at the coming October term of the Supreme Court. Layton's business is in the city of St. Louis.

A Peculiar Infection.—Many people in the vicinity of La Crosse, Wis., are suffering from a strange poisoning received while on the river. The usual form for it to appear is as a large swelling on the part infected, frequently extending to the limbs, and distorting them greatly. The malady is common at this time of year, and makes annual visits. The poison appears to gain entrance to the system through some abrasion of the skin.

Quarantine Against San Francisco Modified.—Dr. Blunt, State health-officer of Texas, has raised the quarantine against San Francisco so as to admit all white people from San Francisco who can show proof of noninfection. He believes that there have been 15 deaths from bubonic plague in San Francisco, and that the disease has become epidemic. The El Paso Chamber of Commerce will make another effort to have the quarantine abolished altogether.

A Crusade Against Quacks.—Dr. S. C. James, the Kansas City member of the State Board of Health, has begun the campaign against quacks that was decided on at the last meeting of the board. He says this is but the beginning of a crusade that will be pushed vigorously all over the State. Dr. James has asked the assistance of the local Board of Health, Prosecuting Attorney E. E. Yates, and the United States Post Office Department in the movement, and from present indications there will be some startling developments.

SOUTHERN STATES.

The Government Hospital Buildings at Savannah, Ga., which cost \$1,000,000, have just been sold for \$17,100.

Police Surgeon Appointed.—Dr. Pinkney Davis, of Baltimore, has been appointed police surgeon in place of Dr. William B. Burch, resigned.

Quarantine Removed.—Dr. Porter has officially removed all quarantines against yellow fever at Tampa, Fla., and declares that no suspicious cases were disclosed by the house-to-house inspection.

Smallpox Eradicated.—The District of Columbia is now free from smallpox. Since last October 75 cases have been reported, with 4 deaths. Recently 4 cases from Lakeland, Md., have been reported to the health-officer of the District.

Fever on Shipboard.—The Norwegian bark "Kotka" has been towed into quarantine at Norfolk. The captain signals that he has Chagres fever on board and some of the crew are reported dead. The Marine Hospital Surgeon has started to visit the bark.

Inspection of Milk.—The New Orleans Board of Health is collecting samples of milk as they come in from the country and testing them by chemical analysis. An inspection was made some time ago, and only two samples were found below standard.

Death-rate of Baltimore.—There were reported in Baltimore last week 197 deaths. Of these 92 were of children under 5 years of age. This heavy mortality of children is attributed by the health authorities to the excessive heat. There were 6 deaths from sunstroke. The death-rate per 1,000 for the whole population was 18.93; whites, 16.92; colored, 32.69.

Cocain Habit Among Negroes.—The City Council of Huntsville, Ala., has passed an ordinance prohibiting the sale of cocain and the refilling of prescriptions calling for cocain. The cocain habit is increasing at an alarming rate among the negroes in the South, and the time is probably not far distant when all Southern cities will find it necessary to enact a similar law.

Adulterated Milk.—Efforts are being made by the citizens of Dallas, Texas, to secure the enactment of the ordinance against the adulteration of foods. A few years ago Dallas had a milk inspector, and the milk-supply was pure, but recently the appropriation for an inspector has been cut off, and at present the adulteration is said to be a menace to the community.

Six Boys Die of Poison.—At Bluffdale, Texas, several boys went into a farmer's watermelon patch and ate and destroyed many melons. Later the boys wrote the farmer a note, telling him they would visit his patch again, and eat more melons than on the previous visit. The farmer split the stems of some of the melons and inserted strychnin. The boys visited the patch and ate of the melons. Two boys died in the patch, 2 on the way home, and 2 after reaching their homes.

CANADA.

The Hospitals of Ontario.—The thirtieth annual report of the hospitals of the province of Ontario shows that there are now in operation in this province of 2,000,000 people 50 hospitals directly receiving Governmental aid annually from the revenues of the province. The number of sick treated in these various institutions during the past hospital year numbered 26,825, exclusive of the thousands known as outdoor patients who receive advice and medicine from time to time. The total expenditure for the year has approached \$500,000. Of this amount the Government contributes a little over one-quarter. In addition to this there are some 40 houses of refuge in the province, 31 orphan asylums, 4 homes for incurables, 3 convalescent homes, 18 county homes for the poor, and 2 Magdalen hospitals, having an aggregate of 10,000 inmates. The Toronto General Hospital admitted 2,986 patients during the year; 3,388 were treated during the year, of whom 206 died. The revenue of this hospital was \$76,633.13 and the expenditure \$79,911.61.

MISCELLANY.

Tents Shipped to China.—Over 650 tents for the use of the hospital department of the American Army have recently been shipped to Taku.

Sick in the Philippines.—The following is Major-General McArthur's official report of the sick in his entire army on July 31, namely: Sick in hospitals, 3,755; sick in quarters, 1,081; percentage, 8.04

Importation from Smyrna Restricted.—The following dispatch has been sent to the consul at Smyrna by the Secretary of State on account of the plague in that city: "Shipment of figs and raisins prohibited. Also, second-hand or used rugs and carpets."

Starvation in Puerto Rico.—A hurricane has devastated a large area of Puerto Rico and as a result the inhabitants are said to be starving. The city of Ponce is suffering most, while in the municipality of Yanco, which has a normal mortality of 60 per month, 400 deaths have been reported in 3 weeks.

Surgeons for China.—The medical division of the War Department is making every preparation for war in China. Already 100 surgeons have been ordered to China, and another detail of 15 men for Chinese service was recently announced. Thousands of applications have been received by the Surgeon-General asking for appointment as contract surgeons for service in China and the Philippines.

Destitution at Nome.—A petition signed by 4,000 persons of Nome, Alaska, has been sent to the War Department asking it to send transports to take them away from Nome before the season of navigation closes. There are between 15,000 and 20,000 people at Nome, and Captain Tuttle, of the revenue-cutter *Bear*, recently reported that 10,000 of this number were penniless, and would be destitute in the fall; in fact, were practically so now.

The Health of Manila.—The president of the Manila Board of Health has completed his report for the army fiscal year which ended June 30. During the months from October to June inclusive, the total number of deaths recorded was 8,535. During this period the total number of deaths, exclusive of Chinese, from various diseases was as follows: Of tuberculosis, 992; beriberi, 242; malarial diseases, 338; diarrheal diseases, 1,073; acute lung diseases, 631; typhoid fever, 41; smallpox, 7; bubonic plague, 180; leprosy, 46; measles, 4.

Yellow Fever.—The disease is said to be increasing in Pinar del Rio, and 50 cases are under treatment in Havana. These conditions are said to be largely due to the advent of nonimmune Spanish immigrants, amounting to about 20,000. The outbreak of yellow fever among the troops stationed at Pinar del Rio, Cuba, is to be officially investigated by a board of army surgeons. It is their purpose to determine why the disease was not properly diagnosed and proper measures taken to avoid the spread of the contagion, and to what extent, if any, the post surgeon should be held responsible therefor, and to submit such recommendations as it may deem pertinent. The board is authorized to proceed to Pinar del Rio if necessary. It consists of Majors William C. Gorgas, Damaso T. Lainé, and Marlborough C. Wyeth, surgeon. United States Consul Thompson, at Progreso, Mexico, informs the State Department that yellow fever seems to be on the increase there, and is virulent at Merida, capital of Yucatan.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended August 10, 1900:

SMALLPOX—UNITED STATES.

			CASES.	DEATHS.

Obituary.—JOHN A. PEARSON, of Bryn Mawr, Pa., August 4, aged 33.—JAMES STOUTON, of Lansingburg, N. Y., at Shanghai, aged 34.—CORTLANDT VAN RENSSLAER CREED, of New Haven, Conn., August 8, aged 70.—G. G. SHANNON, of Tulare County, Cal., August 4.—RIDGELY E. BAER, of Baltimore, August 7, aged 73.—ELIAS B. HARRIS, of San Francisco, August 7, aged 75.—JOHN FRANCIS BURNS, of Long Island City, August 8, aged 37.—J. C. MERRILL, of Portland, Me., August 8, aged 69.—HORACE NEWELL, of Ava, Ill., Au-

gust 8, aged 80.—DAVID CONAHOFF, of Latrobe, Pa., August 10.—W. J. EISTON, of Washington, D. C., August 10.—H. J. COSTELLO, of Philadelphia, August 13.—HERMANN A. LOOS, of New York.

Vivisection.—It is not likely that there ever will be entire unanimity of opinion about the necessity of the practice of vivisection, says the *Inter-Ocean*. However, it is worth while to count over the real additions to scientific knowledge that vivisection has made. A sensitiveness to the infliction of pain or death does not necessarily argue a high degree of love for humanity. The people of India will starve rather than kill a bird, but do not hesitate to expose an unwelcome infant to death. A Hindoo may lay down his own life to save that of a tigress and her whelps, but he will stand unmoved before a widow's suttee. It took a nation that licensed vivisection to put an end to such a horror. For the study of anatomy the dead body suffices, but pathology requires the investigation of living processes. By means of vivisection the circulation of the blood was first understood. Transfusion was first demonstrated to be possible by experiments on dogs. The physiology of respiration was studied by the use of the air-pump on animals, and the effect of vitiated air and its restoration for lung use by growing plant-life was first made clear by means of mice in air-tight receivers. Jenner's experiments with cowpox and their results are widely known. Thierach's experiments in studying cholera have resulted in saving thousands of lives. Present antiseptic methods, which reduced mortality from surgical operations 90%, owe their efficacy to vivisection. Koch and Pasteur came to their knowledge by the same way. The natural mode of the reproduction of bone was discovered by means of vivisection, and thousands have thus been saved from the loss of limbs. When one considers that artificial respiration, by which the drowning and the newborn are so frequently brought to life, the improved surgical operation for the cure of aneurysm, the successful study of the digestive secretions, the investigations of infectious and contagious diseases, the treatment of venomous wounds, the action of poisons, drugs, and medicines, would all be unknown but for vivisection, one must hesitate long before condemning it.

Changes in the U. S. Marine-Hospital Service, for the week ended August 9, 1900:

FRICKS, L. D., assistant surgeon, has been assigned to duty as quarantine officer at the port of Ilo Ilo, by J. C. PERAY, passed assistant surgeon, the chief quarantine officer of the Philippine Islands, which assignment has been approved by the Secretary of the Treasury.

STANSFIELD, H. A., assistant surgeon, has been assigned to duty as quarantine officer at Cebu, by J. C. PERAY, passed assistant surgeon, the chief quarantine officer of the Philippine Islands, which assignment has been approved by the Secretary of the Treasury.

WHITE, J. H., surgeon, to proceed to Mullet Key Detention Camp, Fla., as inspector.

WILLIAMS, L. L., surgeon, to proceed to Stapleton, N. Y., as inspector of unserviceable property.

SMITH, A. C., passed assistant surgeon, leave of absence for 8 days granted by bureau letter of June 30, revoked.

WICKES, H. W., passed assistant surgeon, bureau letter of June 26, granting Passed Assistant Surgeon Wickes leave of absence for 15 days amended so that leave shall be 4 days only.

GREENE, J. B., passed assistant surgeon, granted leave of absence for 23 days.

MATHEWSON, H. S., assistant surgeon, granted leave of absence for 1 month from September 5.

WALKLEY, W. S., acting assistant surgeon, granted leave of absence for 2 days.

RYDER, L. W., hospital steward, granted leave of absence for 15 days from August 1.

IRWIN, FAIRFAX, surgeon, to proceed to Saco, Maine, for special temporary duty.

CARTER, H. R., surgeon, to report at Washington, D. C., for temporary duty.

McINTOSH, W. P., surgeon, detailed as inspector of the Mobile (Ala.) quarantine station.

STIMPSON, W. G., passed assistant surgeon, to proceed to Cairo, Ill., as inspector.

GARDNER, C. H., passed assistant surgeon, granted extension of leave of absence for 9 days.

GOLDSBOROUGH, B. W., acting assistant surgeon, granted leave of absence for 2 weeks, to be taken during August.

WALKLEY, W. S., acting assistant surgeon, granted leave of absence for 2 days.

HEATY, F. J., hospital steward, relieved from duty at Vineyard Haven, Mass., and directed to proceed to San Juan, P. R., and report to Assistant Surgeon C. H. Lavinder for duty.

HOLSENDOFF, B. E., hospital steward, to report at Washington, D. C., for special temporary duty.
 HOLSENDOFF, B. E., hospital steward, relieved from duty at San Juan, P. R., and directed to proceed to Havana, Cuba, and report to the chief quarantine officer of Cuba for duty.
 ESCOBAR, BERNARDO, acting assistant surgeon, quarantine officer at Caibarien, Cuba, died July 28.

Changes in the Medical Corps of the U. S. Army for the week ended August 11, 1900:

RICHARDS, First Lieutenant WILLIAM E., assistant surgeon, Mayaguez, P. R., will report for duty to the commanding officer of the troops en route to the United States, and upon the arrival there will report by letter to the Surgeon-General, U. S. Army, for further orders.
 BENNETT, IRVIN E., acting assistant surgeon, Aguadilla, P. R., will report for duty to the commanding officer of the troops en route to the United States, and upon arrival there will report by letter to the Surgeon-General, U. S. Army, for further orders.
 TANNER, W. T., acting assistant surgeon, Manati, P. R., will report for duty to the commanding officer of the troops en route to the United States, and upon arrival there will report by letter to the Surgeon-General of the U. S. Army, for further orders.
 MCCONATHY, HERBERT M., acting assistant surgeon, Adjuntas, P. R., will report for duty to the commanding officer of the troops en route to the United States, and upon arrival there will report by letter to the Surgeon-General, U. S. Army, for further orders.
 MINOR, JOHN F., acting assistant surgeon, now at the U. S. General Hospital, Presidio, will proceed to Seattle, Wash., to report upon arrival there to the commanding officer, U. S. troops, on the transport "Packling," for temporary duty during the voyage of that vessel abroad.
 DE LOFFRE, SAMUEL M., acting assistant surgeon, will proceed to Seattle, Wash., and report to the commanding officer, First Cavalry, for duty with that regiment en route to Manila, P. I.
 WETHEAILL, First Lieutenant HENRY E., assistant surgeon, will proceed to Seattle, Wash., and will report to the commanding officer, First Cavalry, for duty with the squadrons of that regiment en route for service abroad.
 PINKSTON, OMAR W., acting assistant surgeon, now at the Army General Hospital, Presidio, will proceed to Seattle, Wash., and report on the transport "Athenian," for temporary duty during the voyage of that vessel abroad.
 SMITH, BAT, acting assistant surgeon, is relieved from duty at the Yellow Fever Hospital, Santiago, Cuba, and will report to the commanding officer of the battalion of the Fifth Infantry for duty with that command en route to the United States.
 HENDRICKSON, WILLIAM M., acting assistant surgeon, is relieved from duty at Fort Baker, and assigned to temporary duty at Fort McDowell, to relieve Acting Assistant Surgeon Robert E. Williams.
 WILLIAMS, ROBERT E., acting assistant surgeon, will report for duty as transport-surgeon on the "Hancock."
 WOODBURY, FRANK T., acting assistant surgeon, is relieved from temporary duty at the Army General Hospital, Presidio, and will report to the commanding officer, Battalion, Third Artillery, now at that post, for duty with that battalion during the voyage on the Army transport "Hancock," and for service abroad.
 WAHL, HUGO A., acting assistant surgeon, is relieved from temporary duty at the Army General Hospital, Presidio, and will report to the commanding officer, Battalion, Third Artillery, now at that post, for duty with that battalion during the voyage on the Army transport "Hancock," and for service abroad.
 SMITH, CHARLES F., acting assistant surgeon, will proceed to Holbrook, Ariz., and upon arrival there of troops from Fort Apache, will report to the commanding officer for duty with that command en route to the Philippine Islands.
 WILCOX, Captain CHARLES, assistant surgeon, will upon arrival of the Sixth Cavalry, in San Francisco, Cal., en route to foreign service, report to the commanding officer thereof for duty therewith.
 FULLER, First Lieutenant LEIGH H., assistant surgeon, will report upon arrival of the Third Battalion, Fifteenth Infantry, in San Francisco, Cal., en route for foreign service to the commanding officer thereof for duty therewith.
 STREET, LIONEL A. B., acting assistant surgeon, is assigned to temporary duty with troops en route for foreign service on the Army transport "Meade."
 LEMEN, HARRY R., acting assistant surgeon, is assigned to temporary duty with troops en route for foreign service on the Army transport "Meade."
 SHOCKLEY, M. A., acting assistant surgeon, is hereby relieved from further duty at Cabana Barracks, Cuba, and will report to the chief sanitary officer of the city of Havana for temporary duty.
 FORSTHE, WYLIE H., acting assistant surgeon, is granted leave for 1 month, with permission to visit the United States.
 CALDWELL, ROBERT E., acting assistant surgeon, now at San Francisco, Cal., will report for assignment to duty on the transport "Rosecrans," to relieve Acting Assistant Surgeon James H. Holloway, who will report for assignment to duty on the transport "Sheridan."
 KNEEDLER, HARRY D., acting assistant surgeon, U. S. Army, will proceed from St. Louis, Mo., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

MARSDEN, ROBERT, hospital steward, Josiah Simpson General Hospital, near Fort Monroe, will be sent to the Army General Hospital, Washington Barracks, to join detachment now under orders to go to Fort McDowell.
 TORNEY, Major GEORGE H., surgeon, will proceed to Battle Creek, Mich., and Richfield Springs, N. Y., on business pertaining to the medical department of the Army.
 SIMS, GEORGE K., acting assistant surgeon, is relieved from further duty in the department of California, and will report to the commanding general, department of California, for assignment to duty with troops en route to the Philippine Islands.
 EDMONDSON, JAMES J., acting assistant surgeon, upon being relieved by Acting Assistant Surgeon Robert H. Zauner, will proceed from Fort Du Pont to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 ZAUNER, ROBERT H., acting assistant surgeon, will proceed from Washington, D. C., to Fort Du Pont for duty, to relieve Acting Assistant Surgeon James J. Edmondson.
 MCKAY, JAMES G., acting assistant surgeon, is relieved from further duty in the division of Cuba, and upon the expiration of his present leave will proceed from Philadelphia, Pa., to Fort Sheridan for duty to accompany the Fifth Infantry, under orders for foreign service.
 CLAYTON, First Lieutenant JEFF B., assistant surgeon, is granted leave for 1 month from August 1.
 GODFREY, Captain GUY C. M., assistant surgeon, is relieved from duty in the department of Western Cuba, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to Manila, P. I., where he will report to the commanding general, division of the Philippines, for further orders.
 APPLE, W. EDSON, acting assistant surgeon, is granted leave for 20 days.
 APPLE, W. EDSON, acting assistant surgeon, will upon the expiration of leave proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops en route to China.
 BRECHEMIN, JR., LOUIS, acting assistant surgeon, will proceed from Philadelphia, Pa., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 MABRY, WILLIAM C., acting assistant surgeon, will proceed from Cleveland, Ohio, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 McMILLAN, CLEMENS W., acting assistant surgeon, will proceed from St. Louis, Mo., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 NOBLE, ROBERT E., acting assistant surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 OHLINGER, LORIN B., acting assistant surgeon, will proceed from Allegheny, Pa., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 O'NEIL, JOSEPH A., acting assistant surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 PECK, LUKE B., acting assistant surgeon, will proceed from Brookline, Mass., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 RAFTER, JOHN A., acting assistant surgeon, will proceed from West Winfield, N. Y., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 SHOOK, J. RALPH, acting assistant surgeon, will proceed from Greencastle, Pa., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 STURTEVANT, CHARLES A., acting assistant surgeon, will proceed from West Somerville, Mass., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 WATSON, HENRY J., acting assistant surgeon, will proceed from Ottumwa, Ia., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 WILKLOW, GEORGE, acting assistant surgeon, will proceed from Ellenville, N. Y., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 ADAIR, GEORGE F., acting assistant surgeon, now at Fort Sheridan, will report to the commanding officer at that post for duty to accompany the Fifth Infantry, under orders for foreign service.
 HARBER, J. RANDOLPH, acting assistant surgeon, having reported to the Surgeon-General of the Army, will proceed to Fort Fremont, S. C., for duty to relieve Acting Assistant Surgeon Benj. B. Warner, who will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.
 BAILEY, HOWARD H., acting assistant surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report to the

commanding general, department of California, for assignment to duty with troops destined for foreign service.

ROBERTS, WILLIAM, acting assistant surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

The following named medical officers will accompany the First Infantry to the United States on the Government transport "Rawlins": With battalion from Pinar del Rio—Acting Assistant Surgeons J. F. PARNELL and A. A. NOVEL; with battalion from Guanajay—First Lieutenant E. E. TAVAY and Acting Assistant Surgeon J. F. DUNSHIE.

Changes in the Medical Corps of the U. S. Navy, for the week ended August 11, 1900:

CRAWFORD, C. A., assistant surgeon, is detached from the "Eagle," and ordered to the "Chesapeake."

DELANCY, C. H., assistant surgeon, is detached from the "Constellation," August 13, and ordered to the "Bancroft," August 14.

BRAINSTEAD, W. C., passed assistant surgeon, is detached from the "Massachusetts," and ordered to the "Topeka," August 15.

GARTON, W. M., assistant surgeon, is detached from the "New York," and ordered to temporary duty on the "Massachusetts."

STOUGHTON, JAMES, passed assistant surgeon, U. S. N., was drowned at Shanghai, China, August 5.

Pineapples Furnish a Savage Poison.—The juice of the green pineapple is accredited in Java, the Philippines, and throughout the far East generally with being a blood-poison of a most deadly nature. It is said to be the substance with which the Malays poison their kreeses and daggers, and to be also the "fingernail" poison formerly in use among aborigine Javanese women almost universally. These women cultivated a nail on each hand to a long, sharp point, and the least scratch from one of these was certain death.

Hospital Ship in Service at Taku.—Word has been received that the hospital ship *Relief* left Kobe, August 8, for Taku. The officials are satisfied that she has reached the Chinese port by this time. The *Relief* took the soldiers who were wounded in the engagement at Tien-Tsin and the soldiers who had succumbed to the rigor of the Chinese campaign prior to that event, to Nagasaki, where the United States maintains an excellent hospital. Similar disposition will be made of other sick and wounded soldiers in China, in order to relieve the field hospitals to be established in that country as much as possible.

Dr. Henry E. Menage, of New Orleans, who has been stationed at Manila for the past 18 months, says the American soldier in the Philippines is as healthy as any one possibly could be under similar conditions. If there is a great deal of sickness it is not due to lack of comforts or indifferent supplies. Malaria is always prevalent in the tropics, and it is this ill that has decimated the ranks. Some have dysentery, which results from the impure water they drink when in the field. They have an abundance of fresh meat, which arrives biweekly from Australia in refrigerator ships, and though they do not have all the comforts of home, they want for nothing.

The Board of Control of the Red Cross Association recently held a meeting, and work which the association would probably be called upon to do in case of declared war between China and the nations was discussed. If the conditions justify the Red Cross in taking up its legitimate work in China, it is very likely to do so in cooperation with the Red Cross of Japan. The only nations which have not acceded to the Geneva treaty of the Red Cross are China and Mexico, so that should the Red Cross undertake its work in a war between the nations and China it would have to do so, so far as China is concerned, by a special understanding with that country. This matter was placed in the hands of the president of the association, to take such steps as circumstances may warrant.

Parasite Causing Elephantiasis Found in Mosquitoes.—Reports received from Nigeria, where the scientific expedition recently sent out by the Liverpool School of Tropical Medicine is operating, show that the parasite which causes elephantiasis has been discovered in mosquitoes. The leaders of the expedition believe that the experiments which are now being carried on to stamp out malaria by preventing mosquito inoculation can be applied to elephantiasis, which is so prevalent among natives of tropical countries.

Foreign News and Notes.

GREAT BRITAIN.

Genius Defined.—Mr. Treves, in his lecture to medical students at the opening of the new clubrooms in the London Hospital, says the London *Spectator*, is reported to have said that genius, he took it, was some form of neurosis, an untabulated nervous disease. The few persons of genius he had known had been exceedingly impossible persons, and if there was one profession where genius was out of place it was the medical profession. The thing which in that stood above all else was hard work, and one very peculiar faculty—that of close observation.

House Refuse and Public Health.—At a recent meeting of the County Council of London, a report of the Public Health Committee was considered, and a by-law passed, stipulating that obnoxious matter must be removed in "suitable carriages or vessels, properly constructed, and furnished with a sufficient covering, so as to prevent any nuisance." It is also enjoined that such matter shall not be removed or carried by road in or through London, except during the following periods: "Between 5 and 10 o'clock, A.M., or during the period commencing 2 hours before sunset and ended 1 hour after sunset, in any day during the months of March, April, May, June, July, August, September, and October; between 6 and 11 o'clock, A.M., or during the period commencing 2 hours before sunset and ended 1 hour after sunset, in any day during the months of November, December, January, and February." This important by-law will come into operation when it has been confirmed by the Local Government Board.

The Supplementary Army Estimates.—The Army Medical Service formed the subject of a good deal of discussion on the occasion of the House going into Committee of Supply on the Supplementary Army Estimates, says the *Lancet*. The strength of the medical establishment was dangerously low at the outbreak of the present war in South Africa and it had to be reinforced by the employment of a large number of civil surgeons. Moreover, the occurrences in China, the West Coast of Africa and elsewhere, have vastly increased the demand for medical officers in the public services at present. The present secretary for war did much more than his predecessors had done to restore the popularity of the service, but whether it were owing to want of time or from other causes these measures have not so far been productive of the effect anticipated. As the matter stands the whole subject of the organization of the army medical services and the provision of an independent medical transport and a large medical reserve will have to be taken up and most carefully considered at the close of the present war in South Africa.

The Centenary Dinner of the Royal College of Surgeons was held in the hall of the Honorable Society of Lincoln's Inn, on the evening of July 26. Sir William MacCormac was in the chair and some 300 guests were present, including the Prince of Wales and the distinguished surgeons who received the honorary diplomas of the College in the afternoon. The president proposed the toast of the Queen and the Prince and Princess of Wales. The Prince in responding said he did so in an entirely new capacity, that of an Honorary Fellow of the Royal College of Surgeons of England. He was afraid, however, that he would not be allowed to practise the profession, and if he did he very much feared that he might commit murder, from the results of which even the Lord Chancellor would not be able to save him. He then referred to the great progress made in surgery and to the work done by the profession in the South African campaign. The toast of the Honorary Fellows of the College was proposed by Sir William MacCormac. This is the first time this toast has been proposed, for only recently was the necessary authority obtained to grant these honorary distinctions. The president said that on being asked what principle guided them in the selection of Lord Salisbury and Lord Rosebery as Honorary Fellows, he replied that Lord Salisbury was an eminent man of science and Lord Rosebery was eminent in everything else. All the other Honorary Fellows are surgeons. Lord Rosebery said in reply that he hoped no

one would entrust a surgical case to either himself or the Prime Minister, but that the latter was credited with the intention of performing on the illustrious mother of parliaments an operation which consisted in giving a new lease of life by first stopping that which now existed, and then flinging it into that exhilarating caldron which would return it to life. The toast of the guests was proposed by Mr. Thomas Bryant. He said we have been led to make this selection under the conviction that the Honorary Fellows of this College are men of equal caliber—for the three professing but not practising Fellows are men whom all the world delights to honor, while the remaining Honorary Fellows are the leading practising surgeons of the European and American States and the colonies of Great Britain. The Royal College of Surgeons of England, coupled with the name of the president, was proposed by Lord Salisbury, and Sir William MacCormac responded in an address full of sincerity and gratitude for the kind words spoken. The concluding entertainment of the centenary celebrations took the form of a *conversazione* given by the Lord Mayor of London in the Mansion House.

CONTINENTAL EUROPE.

Imports from Plague Infected Places.—The minister of the interior at Rome has issued an edict revoking the prohibition upon importation of salted hides, hoofs, and shoe leather from places infested with bubonic plague.

Condition of Campagna Peasants.—The Director of the Hygienic Institute of Rome, Professor Celli, has written a book in which he declares that the peasants of the Campagna, about 50,000 in number, are today in a more wretched condition than they were in the time of the ancient Romans. Then they were mostly slaves, but were well-housed and fed, while today they are on the verge of starvation, and there are only about 500 houses for 50,000 persons. In some cases as many as 150 persons of all ages and both sexes live in one large wigwam.

Sanitation at Rome.—Dr. Irving C. Rosse, an American physician who spent some time at Rome as sanitary inspector for the Government, not only discredits the mosquito theory of the origin of malaria, but gives the Eternal City a much better name for salubrity than it enjoys in common repute. He says that malarial fever is seldom seen except among the poorer classes. Americans and Englishmen, in spite of mosquitos and of habits which Italians regard as reckless, now reside there for years without an attack of malaria. He says with the exception of London it is the best drained, best watered, and the healthiest capital in Europe, and a European or native of New England runs greater risk of contracting malaria in Washington.

Army Life Good for Health.—Dr. Carles, a French physician who has given much time to the study of the subject, says that young men who spend a few years in the army have better health than those who remain at home. He says that military service makes men better able to ward off disease. Open-air life, regular hours, frequent exercise are in themselves factors to good health. The latest statistics of the French army show that men who have served for more than a year are far better fitted to ward off disease than those who have just entered the army. Many prominent army surgeons are interested in his statements and the statistics quoted in proof thereof, and are of the opinion that his views are applicable not only to France but to any other civilized country.

Boots and Aniline Poisoning.—It is a common practice to stain brown leather boots black, especially when they are getting old. M. Landouzy, at a meeting of the Académie de Médecine, reported 10 cases of children who, while in good health, were suddenly seized with serious symptoms, such as torpor, coldness, and blueness of the skin, a few hours after wearing yellow shoes recently dyed black. One child, aged 17 months, in the course of a hot day became dull, cyanotic, and asphyxiated, and remained so until the evening in spite of injections of ether and caffeine. In another family 6 children, during very hot weather, were observed by the mother to become blue and tumble down one after the other, and 3 became very ill. A chemical analysis showed that the dyes used consisted of 92% of aniline

and 8% of other coal-tar colors, while experiments proved that the aniline was the real cause of the symptoms, and could be induced in rabbits by merely painting the skin (from which all fur had been removed) with a 92% solution in distilled water, provided that the temperature was kept above 28° C. (82.4° F.). Below 50° F. the application had no effect.—[*Physician and Surgeon.*]

The First International Congress on Medical Ethics, or Deontology, Paris.—On the afternoon of July 25 the Congress divided into two sections, and it was decided that questions of a local character should be discussed in the first and more general questions in the second section. The afternoon in the second section was mainly devoted to the consideration of the many forms of competition from which medical men have to suffer. Dr. Dignat, of Paris, urged that nurses and others who applied water and electric cures were practising medicine, though they were not properly qualified. There was no denying that these agencies might do a great deal of good or, if wrongly applied, a great deal of harm. Then there were the prescribing druggist and the covering doctor. All these were the parasites of the medical profession. Under the supervision of medical men their work was sometimes legitimate and useful, but they had no right to go to families and propose to treat patients unless called in by a qualified medical attendant. Dr. Benedick (Vienna) had always found that the conviction of mesmerists only served to increase the number of their clients. In one case the public prosecutor who had secured a conviction subsequently went himself to consult the quack in question. In Austria also there were many eminent scientists who were not doctors of medicine, and in certain mountainous districts there were no medical men at all. But there were families who had inherited capacities which were probably in the origin based on a true knowledge of medicine. When there was no medical man available the sick could not be prevented from consulting such persons. Also, there were peasants who undoubtedly were wonderful bone setters—one of them had been nominated honorary doctor by the University of Prague so great was his skill. It was wiser to show some toleration to those who outside the profession undoubtedly had rendered services. Dr. Dugron (Paris) said that many patients seen at the hospitals were suffering as the result of **incompetent massage**, and urged that medical students should be taught massage. Dr. C. Petit (Paris) raised the question of the sale of medicaments and poisons without prescription. If poison could not be obtained by itself it could always be bought in the form of a specialty or patent medicine. He thought that these specialties should only be sold when prescribed. Medical men alone could judge whether a special or patent drug was good, but the public were left to decide this matter for themselves on the reading of a pamphlet or advertisement.

On the morning of July 26 the paper on **Deontology**, mentioned in our last issue, was read. The discussion on this communication was opened by Dr. de Gouvêa (Rio Janeiro), who related that medical ethics were at a low ebb till the formation of a medical society in the capital. This produced such good results that similar organizations were created in other parts of Brazil. Dr. Thiéry (Paris) said there should be a book for students explaining the principles of deontology, and it was proposed that there should be an international committee to draw up such a code. The report by Dr. Henry Adler (Vienna) on the **Medical Chambers of Austria** was now read. Many medical congresses had been held before a definite project was approved, and it was in 1891 that a law instituting these Medical Chambers was passed. The law states that all qualified practitioners must be attached to the Medical Chambers, except in the case of a State functionary or an army surgeon, or when a medical man has formally retired from practice. Dr. Paul Schober read a paper on the **Medical Chambers in Germany**, stating that those in Prussia were the best organized. In the afternoon there was some discussion in the first section as to the **relations of medical men with life-insurance companies**, and it was urged that these should be treated as ordinary clients and no special terms made.

Medical Societies.—In the second section Dr. Manolescu, of Bucharest, related that a medical association of Rumanian doctors had been formed. It issued a monthly journal, held

an annual congress, and discussed both sanitary and medical questions. Dr. Cayla described the medical societies of the department of the Seine. Some were 20 and others were 50 years old, but it was only during the last 10 years that they had discussed economical questions. Mr. Adolphe Smith said that the description given corresponded with the general character of the numerous medical societies existing in England, several of which were over 100 years old. These societies were highly respectable and rather than admit the black sheep of the profession had in some instances formed medical unions outside of their own ranks, for it was most necessary to bring into line those who were otherwise likely to become "blacklegs." On July 27 Dr. Lande's paper on **Mutual assistance and insurance for medical men** was read. First he showed the expense in time and money of medical education, and then that the practitioner's income depended on his health, and was rarely sufficient to admit of his saving any considerable sum. Therefore the practitioner should insure his life early when the premiums to be paid would not be high. Dr. Lasale said it was a mistake to believe that all charlatans were outside the profession and illegal practitioners. There were two means of action—conscience and the law. Those who had a conscience had no need of the law; those who had no conscience must have the law. The profession should organize its own police which should warn the public against the charlatans who were within the ranks of the profession. He was in favor of discipline as well as of liberty. While they talked about liberty their difficulties and misery increased. Besides, if liberty was unnecessarily and vexatiously interfered with the profession could easily change those whom it had placed in command. In the afternoon the members all returned to the great amphitheater, where it was decided to meet in 3 years in Belgium.

MISCELLANY.

Dr. G. E. Morrison, the Peking correspondent of the *London Times*, is a physician, 36 years old, and an Australian by birth. He received his medical education in Melbourne and London.

Army Nursing Service.—The Government of India has decided that candidates to be trained as midwives and nurses of the Army Nursing Service should not be under 5 feet 3 inches in height.

Plague in Australia.—The steamer *Aorangi* brings news from Australia of the abatement of the plague because of the cold weather. At Sydney the Board of Health has recommended the issuing of clean bills of health to departing ships.

Obituary.—THOMAS WRIGHT, at Vanburg Park, Blackheath, July 20, aged 68.—HERBERT TAYLOR, of Wisbech, July 19, aged 65.—CHARLES JAMES HYSLOP WARDEN, at Highbury, July 18, aged 40.—WILLIAM URBAN BRICE, at Slough, July 25, aged 83.—ERNEST A. T. STEELE, of Plaistow, July 25, aged 34.

Yellow Fever in Africa.—The French coast in the west of Africa, Senegal, British Gambia, and as far down as Bathurst, has been declared under quarantine on account of yellow fever. The disease is said to be of a very malignant type, and that persons attacked do not, as a rule, survive more than 3 hours.

Infant Feeding.—A law has been passed in France prohibiting anyone from giving solid food of any kind to infants. Persons who give solid food to a child less than one year old, unless it be upon special prescription of a physician, may be adjudged guilty of an attempt to kill. The use of long rubber tubes with nursing bottles is also prohibited, because of the difficulty in keeping them sterilized.

Foreign University Intelligence.—Dr. R. Stern, of Breslau, has been promoted to an extraordinary professorship of internal medicine. Dr. C. Jung, professor of odontology at Heidelberg, has resigned and Karl Gegenbaur, professor of anatomy, is retiring. Dr. Oscar Eversbusch, of Erlangen, has been offered the professorship of ophthalmology at Munich as successor to Dr. von Rothmund, who is retiring. Dr. Ludwig Medicus, of Würzburg, has been appointed to the chair of pharmacy and pharmaceutical chemistry.

Society Report.

BRITISH MEDICAL ASSOCIATION.

Sixty-eighth Annual Meeting, Held at Ipswich, July 31, August 1, 2, and 3.

THE following brief summary will give some idea of the work done and the subjects discussed in the various sections at the sixty-eighth annual meeting of the British Medical Association.

Section of Medicine.

Dr. Judson Bury pointed out that different types of influenza could be recognized according to the particular organs on which the chief stress of the attack fell, but that in all the types the nervous system suffered severely. There were two main groups of nervous disorders associated with influenza; in one the nerve symptoms developed during the pyrexial stage of the disease, and in another during the nonfebrile stage. The first group contained the comatose and delirious cases, and the second the neurasthenic, mental, and paralytic cases. All depended on a general toxemia or on secondary structural lesions produced by the influence of the influenza bacillus either alone or in conjunction with streptococci. Cases were described of lesions of the brain, cord and peripheral nerves, in illustration of these propositions. Sir William Broadbent considered that most of the neurasthenic, neuralgic, and neuritic cases, like those of diphtheria, were due to toxins, but that the comatose cases were due directly to the bacilli, as in some of the malignant forms of malaria, where the meningeal capillaries were choked with the malaria parasites. Five cases of sudden coma due to influenza were described, some of which proved fatal in a few hours, and in one of which a temporary improvement, lasting a week, followed the hypodermic administration of quinin. Allusion was also made to a case with unilateral convulsions, to one with gradual hemiplegia accompanied with active muscular spasm, and to a third who died from paralysis of the respiratory muscles. Sir Peter Eade thought that the toxic influence of the influenza bacilli was exerted more on the sensory than on the motor mechanisms, and that the medulla oblongata had for it a special selective affinity. Professor Clifford Allbutt alluded to the difficulty of the diagnosis of influenza. Its sudden onset was almost pathognomonic. He thought the poisonous effect of the disease fell especially on the anterior part of the brain, and that prognosis of influenzal nervous disorders was not hopeful. Dr. Newton Pitt asked whether the meningitis was due to the influenza bacilli directly or to their breaking down the resistance of the tissues, and thus giving access to the pyogenic and other microorganisms. In one case he had found Fraenkel's pneumococcus, but not the influenza bacillus. He described some cases of postinfluenzal multiple neuritis, and said that the cardiac disturbance was more likely nervous than muscular.

Section of Surgery.

The subject of **Subphrenic abscess** was introduced by Mr. Rickman J. Godlee. Especial attention was drawn to the various causes of the condition, including gastric ulcer, appendicitis, and Mr. Godlee mentioned that in the last 5 years he had seen no fewer than 13 cases of actinomycosis, which was a more common condition than was generally supposed. The many and varying symptoms of subphrenic abscess and its treatment were fully discussed. It was agreed that the character of the aspirated pus did not enable a surgeon to decide whether it had been let out from above or below the diaphragm. Mr. Leonard Bidwell narrated a series of successful cases of pyloroplasty for nonmalignant conditions of the stomach, illustrating the slight risk of the operation. Professor Berg (Stockholm) had found retraction of the stricture recur in 50% of his cases of pyloroplasty, and had been compelled to do gastroenterostomy; he urged that at least three years must elapse before one could consider the cases cured. An interesting case of anastomosis between the gallbladder and colon (cholecystocolostomy), performed for obstructive jaundice due to syphilitic thickening around the common bile-duct, was brought forward by Mr. Betham Robinson. After the operation the patient had completely

recovered under potassium iodid. Mr. F. C. Wallis discussed the causes and treatment of nonmalignant stricture of the rectum, urging that septic infection of some kind was present as the cause in many cases, pointing out in confirmation of this view that synovitis of various joints sometimes occurred as a complication. He adduced 2 cases of extensive excision of the lower strictured part of the rectum; in both the mucous membrane was brought down and successfully united to the anal skin, although some 5 inches had been excised. The result in both cases had been excellent, although in one (in which no preliminary colotomy was done) the shock had been extreme. Mr. Treves stated his belief that many cases of **stricture of the rectum** and other parts of the gastrointestinal tract were due to congenital abnormality, whilst excision could only be carried out in a few cases of fibrous stricture of the rectum, but in these it might prove most valuable. In Mr. Wallis's cases control over the sphincter had been preserved. Mr. Stanley Boyd brought forward the latest results of oöphorectomy in cases of scirrhus of the breast. From these apparently about 40% of the patients were benefited. He did not himself attach importance to thyroid feeding, but Dr. G. E. Herman urged that the combined treatment gave the best result. Mr. Boyd considered the operation practically useless after the menopause, and that it was still in the experimental stage.

Section of Obstetrics and Gynecology.

Dr. Berry Hart opened the discussion upon **Puerperal fever in relation to notification**. In spite of all our progress in antiseptics and the management of labor, the mortality from puerperal fever had not materially decreased. Dr. Hart discussed the advantages of notification, the difficulties of carrying it out, the way it should be done, and the measures which should follow it. The circumstances under which it should be recommended for any district, and the necessity that such district should be provided with isolation hospitals to which suitable cases could be removed. The President read a communication from the Local Government Board pointing out that "the object to be attained, in so far as preventive medicine was concerned, was to bring to the knowledge of the sanitary authority all those conditions which, supervening upon parturition, were communicable from one parturient woman to another," and also a statement from a medical officer of health that his experience of notification had been disappointing, the deaths from puerperal fever in one or two years having in his district exceeded the notifications, and that, except for disinfection of bedding at the end of a case, the intervention of the M. O. H. was seldom necessary. The sense of the meeting was that to make the notification a privileged communication between the medical attendant and the officer of health was impracticable, and at the close of the discussion it was resolved unanimously, on the motion of Dr. Boxall, seconded by Dr. Beverley, that it be a recommendation to the Council that in the opinion of the meeting it was desirable that notification of puerperal fever (septicemia) should be adopted generally.

Section of State Medicine.

Dr. Nathan Raw read his paper upon tax supported **Sanatoriums for consumptives**. He described what had been done in Liverpool, and felt sure that in a very few years sanatoriums would have to be provided at the expense of the State, since no one with phthisis would be able to get employment. Dr. Houston next introduced a discussion upon "Can modern systems of sewage treatment be depended upon to remove the *Bacillus typhosus* and allied organisms?" He described a number of his own experiments and generally came to the conclusion that modern methods had not yet solved the problem of getting rid of the pathogenic bacteria.

Section of Physiology.

Professor Halliburton proceeded to open a debate on the **production of uric acid**. He dwelt on the physiologic side of the question, as it is necessary to know the normal history of uric acid before its abnormal behavior can be unraveled. He advocated an extension of Horbaczewski's views on the formation of the acid from nuclein; there are probably several factors concerned—namely, the nuclein and

purine compounds of the food, and that which results from the metabolism of the nuclei of leukocytes and other cells. He also pointed out that uric acid is only one of the so called purine compounds, and that all of these substances must be considered in any wide survey of the subject. He drew attention to another error into which some investigators have fallen—namely, in regarding the uric acid in the urine as the amount which is produced in the body.

Section of Pathology.

A discussion on the **Pathological distribution of *Bacillus diphtheriae* and the bacteriological diagnosis of bacterial infections** was introduced by Dr. Andrewes, who referred to the impossibility of giving a certain diagnosis within 24 hours, as clinicians were apt to expect. He said that the question of the diagnosis of diphtheria had to be looked at (a) from the strictly scientific, and (b) from the clinical point of view. From the first standpoint it might be a week or more before a certain diagnosis could be given, but such a delay would render the bacteriological diagnosis valueless for the physician. From the clinical standpoint it was necessary, in his opinion, to have full information of the clinical aspects of the case before giving an opinion upon the bacteriological data, owing to the impossibility of giving a certain opinion in the case of an organism culturally and morphologically indistinguishable from the diphtheria bacillus without resorting to animal experiment. Professor Muir read a paper on a case of serious anemia and purpura associated with great deficiency in the red bone marrow. The case, that of a boy of 14, showed, clinically, an anemia reaching to 600,000 red blood-corpuscles per c.mm., together with severe hemorrhages, and death within 8 weeks of the onset of the disease. Pathologically, there was a complete absence of the usual vascularity found in cases of profound anemia; and on the contrary, the marrow of the femur and of the ribs simply consisted of fat. He discussed the question as to whether the medullary condition was the primary lesion.

Section of Ophthalmology.

The first discussion was opened by Mr. Richardson Cross on the **Treatment of chronic glaucoma**. He based his remarks upon 47 cases of the disease which had occurred during his private practice, and which had been very carefully tested. In his diagnosis he relied to a very great extent by the condition of the field. He discussed at length cases treated with myotics and also by operation, and showed many fields of vision, most of which demonstrated the fact that the fields improved after the tension was removed. He thought that sclerotomy was a most useful operation, and he preferred to do this operation with a keratome rather than with a Graefe's knife. He expressed himself strongly in favor of early operation.

Section of Diseases of Children.

Dr. Nestor Tirard read a paper on the **Nature and varieties of pneumonia**, in which he referred to the main types of the disease and their relation to one another. He discussed the questions of general infection and the employment of antipneumococcic serum, contagion, and the association of pneumonia with other infective diseases such as influenza. The various kinds of temperature seen in the disease were noted, and the duration and various initial symptoms, especially those associated with abnormal or deficient physical signs, were discussed. The bad prognosis in certain cases was alluded to and explained.

Section of Pharmacology and Therapeutics.

Dr. Walter G. Smith (Dublin) proceeded to open a discussion on the **Treatment of internal hemorrhage**. He observed that a few cases of hemorrhage from the lungs, bowels, or kidneys were in themselves fatal or imminently dangerous. Patients died after hemorrhage, but not often of it (S. West). Many cases of hemorrhage stopped naturally if only let alone. Hence drug treatment of hemorrhage was often superfluous and sometimes mischievous. The efficacy of local styptics was undoubted, and their *rational* quite simple. Gallic acid was devoid of local styptic power, and tannic acid was excreted partly as alkali-tannate and partly as gallic acid, neither of which coagulated albumin nor con-

stricted bloodvessels. Hence tannic acid was useless as a remote hemostatic. The most rational treatment of, say, a serious case of hemoptysis, consisted simply in mental and bodily rest, administration of morphin, and free evacuation of the bowels.

Section of Laryngology and Otology.

Indications for the intranasal treatment of ear disease formed the subject of a discussion which was introduced by Dr. McBride, Mr. Cresswell Baber, and Dr. Dundas Grant in papers which will appear in the full report. The president remarked that with regard to nasal obstruction we were in need of a fixed standard. Was reduction of pressure the essential thing? When could improvement be promised to the patient, or even a stationary condition? Dr. Herbert Tilley said he had never seen any improvement of hearing in chronic nonsuppurative cases from the removal of nasal obstruction. He would not even promise arrest. In the cases of moist catarrh it was different. Dr. Horne thought age had a good deal to do with it. In children the nasopharynx was small, and removal of nasal obstruction gave brilliant results—much better than were obtained in adults in whom the nasopharynx was more roomy. Dr. Watson Williams regarded the catarrh as the essential thing rather than the obstruction. The influence of "negative pressure" was largely hypothetical. Mr. R. Lake thought all cases of chronic dry catarrh were nasal in origin, but the cases which could be benefited were those in which air-conduction was not very much shortened, and in which there was fair mobility of the malleus. Most good was done by the removal of the more posterior nasal obstructions, such as posterior hypertrophic rhinitis. He disbelieved in the "negative pressure" theory, and thought nasal obstruction acted by setting up mucous catarrh, causing constant hawking efforts to clear the nasopharynx. Dr. Holbrook Curtis (U.S.A.) claimed excellent results from intranasal operations both in catarrhal and sclerotic cases. Anemia was relieved and oxygenation increased. He objected to the term "negative pressure" as unscientific.

Section of Tropical Diseases.

Dr. Andrew Duncan read a paper on **The action and modes of employment of quinin in malaria.**—Mr. Carré believed quinin diminished the chance of infection in the simpler forms of fever, but was well nigh useless in the pernicious forms. M. Marand was of a similar opinion. The evidence of Russian and Austrian army surgeons found no advantage from quinin as a prophylactic. M. Pola experimented on 726 soldiers; of 500 who took quinin 18% were attacked, whilst of the remainder who did not take quinin 28% had malarial attacks. Of American physicians Dr. Bryan found quinin and cinchona to be true prophylactics. Dr. Duncan's own observations amongst Sikhs and Goorkhas was in favor of quinin as a prophylactic. On the West Coast of Africa, among 133 observations recorded, the drug was efficacious in 87.7%, but gave no result in 12.3%, showing a marked prophylactic power. No drug could be compared with quinin in efficiency, either as a prophylactic or as a curative agent. Injection of quinin by the rectum was recommended when exhibition by the mouth proved disappointing. Major W. I. Buchanan, I.M.S., communicated a favorable paper on the **Prophylactic issue of quinin—a synopsis of an experiment on a large scale of Indian jails.** He stated that he had never seen a case of hemoglobinuria, nor had he ever heard of a case since the administration of quinin was introduced into the prisons of India. Dr. Fielding Ould communicated a paper on **The administration of quinin, with special reference to the practice on the west coast of Africa.** He contended that so long as there was no gastric irritation administration by the mouth was most satisfactory. Rectal injections of quinin were highly efficacious; its subcutaneous injection was reliable. He deplored Koch's doctrine as to the dangers of quinin. A discussion on the three papers read then took place. Lieutenant-Colonel Maitland, read a paper on the **Etiology of filariasis**, in which he contended that the discovery of the filarial worm passing along the proboscis of the mosquito was not conclusive proof that the old idea of infection by water was wrong. He remarked upon the immunity of Europeans in India from filaria, and

ascribed it to the fact that they drank for the most part only boiled or filtered water. Captain S. P. James communicated a paper on the **Metamorphosis of filaria sanguinis hominis in mosquitos**, especially with reference to its metamorphosis in the *Anopheles Rossii* and other mosquitos of the *Anopheles* genus.

Section of Navy, Army, and Ambulance.

Surgeon Lieutenant-Colonel J. E. Squire read a paper on the **Augmentation of the Royal Army Medical Corps.** He urged that an advancing army should be relieved of its sick and wounded as rapidly as possible, and that a large medical *personnel* was therefore requisite. He considered untrained medical officers and nurses would prove a hindrance, and that a reserve should be arranged for, whose efficiency should be provided for by their being borne as supernumerary in the volunteer forces with a retaining fee for efficiency, and with pay when voluntarily training subsequently. He deprecated civilians being incorporated with military units, though they should be under military control. Mr. Frederick Treves observed that transport for field hospitals had been questioned, but that all field hospitals have their own transport, and that transport is admirable. The present campaign has shown the value of a large mobile field hospital (taking 300 to 600 beds) to immediately follow the column. This hospital should have its own transport. This was so in Natal, and it made the efficiency of the hospital perfect. That the R. A. M. C. and the civil surgeons worked in perfect harmony throughout, a fact largely due to the unselfish attitude taken by the former officers. He considered the question of orderlies is a difficult one; that the present campaign showed that female nurses, keenly as their services were appreciated, could not work in field hospitals, but that in the base hospitals their number could be greatly increased with advantage. Surgeon-Captain James Cantlie in conclusion moved: That the Navy, Army, and Ambulance Section requests the Council of the British Medical Association to appoint a committee to draw up a scheme to be forwarded to Government, for the reorganization of the medical services of the auxiliary forces, on the basis of the system in the Royal Army Medical Corps, and for the purpose of bringing the medical services of the regular and auxiliary forces into unison.

Mortality from Snake-Bites in British India.

From the latest report on the destruction of wild animals and snakes in India it appears that during the last 10 years an average of 21,000 human beings have been killed annually by venomous snakes. With a view to mitigating this heavy mortality, the Government of India has for many years past been offering rewards or head-money for the slaughter of all known species of venomous snakes. Notwithstanding the payment of large sums annually for the destruction of these reptiles, the results have hitherto been most discouraging, and of late it has become a serious question whether any benefit is to be derived from the payment of these rewards. The mortality continues very heavy and snakes appear to be as numerous as ever. The natives have been suspected of breeding snakes for the sake of the rewards offered for them.

Propagation of Plague.—Recent investigations attribute an even closer connection between rats and the propagation of the plague in the East. In a Bombay cotton factory, where a number of dead rats were removed by coolies, about half the number developed plague inside of three days; while none of those who had not touched the rats contracted the disease. It is suggested that plague can also be communicated by the fleas natural to the rats. A perfectly healthy rat will harbor few fleas, as the animal is particularly expert in removing them, but when the rat is sick the fleas are abundant. After death the fleas leave the rat's body, and on reaching another rat or a human being, they may inoculate the bacilli they acquired by ingesting the blood of their former host. In an experiment in support of this theory, it was found that if sick and healthy rats, in separate cages, were enclosed in a glass jar, the healthy animals did not become infested when there were no fleas present.

2.—From a study of the **physiologic action of senecio Jacobœa** Bunch concludes: 1. That injection of small doses of an alcoholic extract of the entire plant into the circulation of the dog causes a rise of the general blood-pressure, with constriction of the peripheral vessels and of the vessels of the intestinal area. This effect is accompanied by a diminution in the magnitude of the contractions both of the auricle and of the ventricle. 2. That large doses (0.8 to 1.0 gm. for a dog weighing 7 k.) of the drug cause a fall of general blood-pressure with dilation of the intestinal vessels and inhibition of the contractions of the intestinal coats. 3. That after several injections of small doses or after one large dose of the alcoholic extract, further injections produce a fall of blood-pressure, with slowing of the heart, and this effect is repeated unless a considerable interval is allowed to elapse before any further injection of the drug, which then again causes some rise of general blood-pressure. 4. That the entire plant, therefore, contains two substances with distinct physiologic actions, which have not yet been isolated. 5. That watery extracts of the residue obtained by evaporating the alcoholic solution produce a fall of blood-pressure and cardiac inhibition, due to the action of the drug on the nerve-terminations in the heart and not to direct action on the muscular fibers of that organ. 6. That the substance that causes a rise of blood-pressure is not contained in such watery extracts or, if present, only in small quantities. [J.M.S.]

3.—Hunter again calls attention to the fact that the constant **swallowing of pus** is a most potent and prevalent cause of gastric trouble. The catarrh set up in this way is not simply irritant, but actually infective, and may lead to atrophy of the glands, chronic gastritis, and, in certain cases, to suppurative gastritis. The subject of **oral sepsis** should not be confined to any one pathologic condition of the mouth, such as pyorrhea alveolaris, but should include all forms of dental and oral trouble produced by septic infection. False tooth plates, crowns, and bridges give rise to cases of stomatitis or gingivitis by the retention of foul matters. The pus organisms of **dental caries**, like those of all necrosing bone, are particularly virulent. The matter is important not only in the production of gastritis but also in the pathogenesis of many local and general infections. Oral antisepsis may be obtained: 1. By the direct application to the diseased tooth or inflamed gum of 1 to 20 carbolic acid, repeated daily as long as the cause is present. 2. By the removal of all diseased and useless stumps. 3. By the scrupulous daily sterilizing by boiling of every tooth plate worn. 4. By the avoidance by dentists of too much conservative dentistry and the use of bridges that cannot be kept aseptic. [J.M.S.]

4.—Maylard describes the symptoms of a man of 35 who for 18 months had suffered from a troublesome bowel complaint. The trouble consisted of constipation, passages of mucus and flakes of lymph, and pain especially late in the

course of the disease. An enema was necessary to cause a movement. The pain was severe about the eleventh and twelfth ribs on the left side and in the axillary line; but its place of greatest intensity was in the epigastrium. The pain was always more severe when the patient was in the sitting posture. Flatulence was marked at times. It was very difficult to diagnosticate the condition, and it was thought he had membranous colitis and colostomy had been considered. Rather suddenly there appeared a pulsating tumor in the left lower dorsal region close to the spine. It was at once seen that this was an **aneurysm**, which by pressure upon the nerve-trunks had caused the diffuse pain and by pressure upon the bloodvessels supplying the intestines had caused a chronic congestion of those organs, and hence the bowel trouble. The aneurysmal tumor pointed backward, a very rare condition. No necropsy was permitted. [A.B.C.]

5.—From experiments on the mongoose Elliott gives the average dose of **cobra venom** that will kill one of these animals as 0.006 gm. per kilogram of body-weight. Some healthy and active animals, however, can bear a much larger dose; Calmette in his experiments obtained a somewhat smaller dose; but he experimented with animals obtained from Guadeloupe, which had been away from poisonous snakes for at least 25 years, and this leads to the conclusion that the immunity possessed by the mongoose is acquired, and that absence of poisonous snakes in a country reduces this immunity. Taking the rabbit as a unit of susceptibility to cobra venom, we find that the dog is 2 and the mongoose from 10 to 25 times as resistant. After watching a number of fights between the cobra and the mongoose the author concludes that during the open phase a mongoose is likely occasionally to receive incomplete bites in which only very small quantities of venom are injected into its body. When the mammal seizes the snake's head in its mouth and drives its bladed teeth through the poison sacs the escaping poison must often pass down its throat and be swallowed. In both of these ways it is likely that a gradual immunizing process takes place, a process that is kept up through successive generations so long as the animals are in constant contact with poisonous snakes. The snakemen of South India are certainly ignorant of any method of producing in themselves a highly-developed immunity. Some of them swallow venom and others rub it into their limbs, whereby it is possible that they obtain some degree of immunization. The snakemen confine themselves almost exclusively to the cobra and escape harm by their intimate knowledge of the methods of handling this snake. [J.M.S.]

6.—Lodge describes the case of a man of 22, who complained of stiffness of the right knee; at first it was during the day, but later became constant. The knee became much swollen, and the cutaneous veins were enlarged. The enlargement was due to increased size of the tibia in the popliteal region. A trephining of the tibia was done 6 months after the onset of the symptoms. There was no pus nor any sign of abscess. Soon he was seen by Teale, and that surgeon advised amputation because he believed the growth malignant, which by microscopic examination was proved to be correct. Amputation was done and the patient appeared to recover completely, but about 9 months later his hands began to enlarge. They became enormous in size, symmetric, and possessed very little mobility. His mind became clouded, and he died about 20 months after the onset of the disease. The author is of opinion that the etiology of this condition was similar to that of the **acute malignant form of akromegaly**. [A.B.C.]

7.—McVeagh was called by a midwife to see a patient who was suffering from some unusual accident, and upon his arrival found a case of **inversion of the uterus** with the placenta adherent all over the inverted surface. He attempted the reduction at first without removing the membranes, but finding it impossible to succeed in this way he separated the secundines completely (hemorrhage ceasing immediately), and after working for about three minutes was rewarded by its reduction with an unmistakable flap. The patient made an uneventful recovery. [W.K.]

8.—Eddowes records the case of a girl whose sclerotics were so transparent that the pigment of the choroid could be seen through them. This patient had had many fractures, one from very slight violence, and she said that her father's eyes were like her own, and that he had several times broken bones, one even by putting on his coat. The

author also knows of a boy whose sclerotics were very dark, and who in 2 years had 9 independent fractures. The author is of the opinion that the **transparency of the sclerotics** indicates a want of quantity or of quality of the fibrous tissues, which, in turn, is a factor in **fragilitas ossium**. [J.M.S.]

9.—Greene reports a case of **hysteric convulsions** occurring in the person of a man, 26 years of age. An ingrowing toe nail appeared to be the hystericogenic spot. [J.M.S.]

10.—Weir reports the case of a Rajputin who came under his care in a hospital in Sutna, complaining of what she described as a prolapsed womb. It proved to be a **fibromyoma** the size of a large cocoanut originating from the upper part of the anterior vaginal wall. On emerging from the vulva, which event was dated about a year before the patient consulted him, the tumor brought down with it the urethra, part of the bladder, and the anterior vaginal wall, and the os uteri could be felt behind the tumor just inside the vulvar opening. The tumor was readily enucleated, and healed rapidly. The patient was discharged cured on the eighth day after operation. [W.K.]

11.—Buckell reports a fatal case of **tetanus**. The patient was a boy of 12, and at autopsy no skin-wound could be found as an entrance-point for the organisms and no gross change of any of the viscera was observed, except congestion of both lungs. Twenty cubic centimeters antitetanic serum was administered without effect. [J.M.S.]

12. A Case of Congenital Hypertrophic Stenosis of the Pylorus. EDMUND COURTLEY.
13. A Case of Hydatid of the Liver and Suppurating Hydatid of the Left Lung. RUTHERFORD MORISON.

1.—Robson considers **pancreatitis**, particularly in its simulation of **carcinoma of the pancreas**, and details 7 cases illustrative of operative treatment. In the chronic interstitial variety he advocates operation at the earliest possible moment. For attacking the head of the pancreas or the pancreatic duct a vertical incision should be made through the right rectus and not in the middle line. When deep jaundice is present he gives calcium chlorid in 20 grain doses 3 times daily for 24 or 48 hours before operation and in the form of an enema for 24 hours afterward in 60 grain doses thrice daily. Of 17 patients upon whom he has operated and found chronic pancreatitis to be the obvious disease present, 16 have recovered, while in cancer of the pancreas in 16 patients operated upon, only 9 recovered from the operation, the ultimate duration of life thereafter being very brief, leading to the conclusion that when cancer of the pancreas is surely diagnosed operative treatment is either useless or harmful; when the diagnosis is doubtful, especially in young or middle-aged subjects, exploratory operation should be seriously considered, since much may be hoped from surgical treatment in inflammatory conditions. [M.N.T.]

2.—In treatment of **hammer-toe** Haward advocates

manipulation of muscles, friction, and tiptoe exercises. Attention should be given to general health. If the extensor tendons are persistently contracted they should be divided. In pronounced cases amputation at the metatarso-phalangeal joint by oval incision, leaving the scar on the plantar surface, is advised. In most cases Haward excises the head of the proximal phalanx; he turns back a semilunar flap from the dorsum of the toe, divides the lateral ligaments, thrusts the head of the bone out of the wound, and excises by bone forceps. The toe is then straightened, the skin united by sutures and the foot kept in a splint 3 weeks. Fibrous union occurs between the bones and the toe remains straight and gives no further trouble. [M.B.T.]

7.—Berland had 265 patients convalescing from enteric fever, and 82 patients convalescing from dysentery under his care as medical officer of an army hospital transport running between South Africa and Southampton. In 56% of the cases of **enteric fever** the pulse-rate was 80, in 25% it was 95, in 10% it was 100, in 5% it was 110, and in 4% it was between 120 and 140. The pulse-rate in 50 patients convalescing from dysentery was between 72 and 80. The author calls attention to the fact that the majority of enteric fever convalescents had been grievously debilitated by fatiguing marches and by poor and irregular feeding, so that the heart was in an irritable condition before the attack of enteric fever developed, and that disease, of course, did not tend to allay the cardiac condition. He assumes that the **tachycardia** was the inevitable sequel of such conditions. In the case of a soldier who had been on garrison duty, and a ship's fireman, patients who were not debilitated before the attacks of enteric fever that they had, the tachycardia was not observed. [J.M.S.]

8.—MacFadyen and Rowland exposed *Bacillus acidilactici*, *Bacillus typhosus*, *Bacillus diphtheriae*, *Protens vulgaris*, *Bacillus anthracis*, *Bacillus coli communis*, *Staphylococcus pyogenes aureus*, *Spirillum cholerae*, *Bacillus phosphorescens*, *Bacillus pyocyaneus*, a sarcina, and a yeast growing in both cultures to a temperature of 52° C. for 10 hours. The cultures were sealed in thin glass tubes and introduced directly into liquid hydrogen contained in a vacuum jacketed vessel immersed in liquid air. At the end of the experiment the contents of the tubes were examined microscopically and by culture and there was no appreciable alteration in appearance or in the vigor or growth of the microorganisms. [J.M.S.]

9.—Jones relates a case of actinomyces treated by potassium iodid in increased doses from 30 grains a day to 240 grains a day in 6 weeks. The patient had no unpleasant symptoms from the drug, but put on flesh; recovery resulted. [M.B.T.]

10.—Neave reports the case of a married woman, aged 31 years, who complained of breathlessness, palpitation, and weakness, and presented the majority of the typical features of **chlorosis**. The patient fainted more than once; she had a severe attack of vomiting with severe headache, she had a feeling of numbness in the left arm and leg, so that these members felt dead; she had great pain over the vertex of the skull and in the frontal region; her memory was confused, and she was slightly delirious. A diagnosis of **thrombosis** of one or other of the **cerebral veins** or sinuses in the region of the right motor was made after all forms of secondary thrombosis had been excluded. The patient recovered. [J.M.S.]

11.—Beveridge reports a case of **abscess of the parotid gland** spreading forward over the cheek and upward over the temporal region, thence downward and backward behind the ear, where it finally pointed, tilting the ear forward. On incision a considerable quantity of purulent matter was evacuated. The source of infection was doubtless through the tonsil, but in this case the pus worked its way forward, passed under the zygomatic arch backward beneath the temporal fascia, escaping under the lower border to reach the surface. [M.B.T.]

12.—Courtley reports the case of a female infant, aged 3 months, who died the day after admission to the hospital. The child had been sick ever since her birth, the principal symptoms being constant vomiting, constipation, and wasting. She weighed 6 pounds 3 ounces, had occasional slight convulsive movements, and had a temperature of 105° just before death. At the necropsy the stomach was found to be greatly dilated; its walls were thin, except in the pyloric

region, where they were thicker than usual. The pylorus formed a definite, elongated, cylindrical tumor, nearly an inch long, and firm and hard in consistency. On opening the duodenum the pylorus presented the same appearance as the os uteri when seen from the vagina. Occlusion of the orifice was completed by the folds of mucous membrane and the liquid stomach-contents could not be forced through it, although a small probe could be passed into the stomach. When the pylorus was laid open by a longitudinal incision the mucous membrane was seen in a thick, raised fold that bifurcated into the mucous membrane of the stomach. The wall was $\frac{3}{8}$ inch thick at the duodenal end, but thinner toward the gastric end. The increase in thickness was due to an hypertrophy of the circular layer of muscle. Remarks on the frequency of **congenital hypertrophic stenosis of the pylorus** and theories to account for its cause follow. Pylorectomy is the treatment that offers the best chance of success. [J.M.S.]

13.—Morrison reports the case of a patient admitted complaining of swelling of the right side. The first symptom noticed was pain below the right breast and at the top of the right shoulder, increased by deep breathing and swallowing. The pain on swallowing was so marked that the condition was attributed to indigestion. She continued about her housework for three years when she had severe pleuritic pain in the left side. After a violent fit of coughing, almost a gallon of mucopurulent material was expectorated. On percussion of the swelling in the right hypochondrium, which was particularly noticeable after this attack, it was possible to obtain a hydatid thrill; the liver-dulness was increased. A diagnosis of **hydatid of the liver** was made, and the contents of the cyst were evacuated. The physical signs of empyema having been found at the base of the left chest a week later, a collection of pus in the lung, with a number of hydatid cysts, was evacuated. She was discharged completely cured 2 months after the first operation. [M.B.T.]

New York Medical Journal.

August 11, 1900. [Vol. lxxii, No. 6.]

1. An Investigation into the Causes of So-called Uric Acid Lesions, and a Rational Therapeutics of the Uratic Diathesis. ALFRED CARENO CROFTAN.
2. The Etiology of Diphtheria and the Value of Antitoxin. A Further Criticism on Dr. Herman's Views. A. ROBIN.
3. The Spectacle and Eyeglass Habit. ALFRED W. HERZOG.
4. The Relation of Seminal Vesiculitis to Impotence. RAMON GUITERAS.
5. Obstetrical "Don't Fails." CHARLES I. PAGE.
6. The Diagnostic and Therapeutic Value of the Esophagus, Stomach and Colon. C. D. SPIVAK

1.—Uric acid is an insoluble, nontoxic substance and is incapable of producing the vast array of symptoms commonly attributed to its presence in the blood of uratic patients. On the other hand, the **alloxuric bases** are readily soluble in the tissue juices and are highly toxic, so that they can produce a series of functional disorders that are similar to, if not identical with, those observed in the "masked" forms of so-called uric-acid intoxication; they can also produce the anatomic kidney-changes that are identical with those found in gout. Although it has not been demonstrated experimentally that the alloxuric bases are responsible for the joint-lesions of gout, yet, by analogy, we are justified in assuming that they prepare a nidus in the joint-tissues suitable for the secondary deposit of urates. From a study of the histogenesis and chemic relations of uric acid and the alloxuric bases it is learned that the formation of uric acid is in reality a conservative and protective process of disintoxication. Whatever the primary or remote cause of the uratic diathesis, the nature of the taint is an excessive nuclein katabolism; that is, a tendency on the part of the uratic subject to disintegrate a quantity of nuclein in excess of the normal. At first, the normal oxidation processes are capable of converting almost all the nuclein into uric acid, which is duly excreted by the kidneys; at the same time, small quantities of the poisonous alloxuric bases are formed that enter the circulation and pass through the kidneys, there producing toxic influence and laying the founda-

tion for the anatomic changes in the kidney parenchyma. As the self-intoxication progresses in severity, the vital processes fall below par and therewith oxygenation is reduced. When this takes place even less of the nuclein that is being disintegrated can be converted into innocuous uric acid and more of the toxic alloxuric bases are formed in its stead. As the disease progresses in severity, whether in the natural course of the affliction or aided by indiscretion in the mode of life, the chronic intoxication goes on. It is during this period that the inflammatory and neurotic changes occur in the joints, the kidneys, and in other organs, preparing a field for the formation and deposit of urate concretions. The urate concretions then act as foreign bodies and set up tertiary inflammatory changes. In the last stages the oxygenation is reduced to the minimum, the formation of uric acid ceases altogether and only alloxuric bases are poured into the blood. Finally, the kidneys become incapable of excreting any solids and **acute alloxuremia**, "uremic poisoning," terminates the syndrome. In these lines there are 3 directions in which **therapeutic measures** should be instituted. 1. An attempt should be made to increase the elimination of the toxins as they are formed. 2. Nuclein katabolism should be reduced. 3. The oxygenating process should be increased. The articles of food that contain nucleins, nitrogenous extractives, and those that produce leukocytosis should be excluded from the diet of an uratic patient. All other articles of food should be permissible except those that by producing gastrointestinal irritation of any kind prevent the normal process of assimilation and engender lactic-acid fermentation. In order to raise the oxygenating process of the organism, iron, arsenic, and the usual tonics are indicated and the inhalation of oxygen gas may be used with excellent results. [J.M.S.]

2.—The paper is an argumentative one, designed to disprove criticisms made on a former article by the author that appeared in the *International Medical Magazine*. It presents the evidence for antitoxin in a satisfactory manner, although the sentences are at times quite personal. [J.M.S.]

4.—Gui érás finds that **atonic impotence** is in many cases due to **seminal vesiculitis**. In the treatment of the condition he uses internal remedies to neutralize a hyper-acid urine, nightly rectal irrigation with normal salt-solution or strained flaxseed-tea at a temperature of 105° to 120°, and massage of the internal genitals every 5 days, followed immediately by an urethral irrigation whenever there is an associated chronic prostatitis or posterior urethritis. After the symptoms of inflammation and irritation have been relieved tonics and electricity may be employed. Outlines of 7 cases are given. [J.M.S.]

6.—Spivak describes a stomach-tube in which he made an additional opening just below the line for the teeth, so that the patient may, by shutting the mouth and blowing, distend his own stomach. He recapitulates the **diagnostic value** of this procedure, and also the use of **insufflation of the colon and esophagus**. [J.M.S.]

Medical Record.

August 11, 1900. [Vol. lviii, No. 6.]

1. American Medicine. JACOB.
2. The Care of Patients during Surgical Operations; with Some Methods of Preventing Shock and Infection. FENTON B. TURCK.
3. After-Pains from Extraction of Teeth. CHARLES B. ISAACSON.

2.—After the usual cleansing for operation, Turck recommends applying a **sheet of thin rubber** which fits closely to the body and is held in place by straps and buckles. The usual laparotomy sheet may be used in addition. The rubber protective diminishes danger of infection from the skin, prevents contamination of the skin, and reduces the tendency to shock by protecting the exposed area and preventing loss of heat by evaporation. If the central opening in the sheet, over the site of operation, is cut in flaps these may be folded over the wound-margin and into the peritoneal cavity, excluding wound-margins, skin and peritoneum from the field of operation. For operations such as anastomosis of the viscera, etc., in which there may be possible contamination from the opening of a viscus or a pus-cavity, he advocates

the use of a square sheet of rubber dam with one or more small openings, reinforced by rubber bands forming a collar, the distance between the openings varying according to the operation. This **protective shield** is laid over the abdominal wound and the portions of the stomach or intestines to be incised, drawn through the opening. This portion of the viscera is thus excluded from the abdominal cavity, and the constriction band retards undue escape of contents, at the same time keeping the contaminated material on the outside. At the conclusion of operation the sheet is readily removed by dividing it with scissors. He claims for this procedure the following advantages: Exclusion of the abdominal cavity from the danger of infection by escape of visceral contents or through outside influences. Prevention of excessive escape of visceral contents. Partial or perfect hemostasis by pressure by the rubber collar. Reduction of trauma of the viscera; being covered they are less liable to injury. The "collar" holds them in position and there is no need of tugging and pulling. Minimizing of the tendency to shock by handling, exposure, evaporation, and loss of heat. In the application of heat to the viscera by hot sponges during celiotomies the heat is soon dissipated and the sponges cannot be changed frequently enough. Turck uses a small thin rubber hot-water bag, placed within a gauze pad. The temperature found most useful is about 45° C. Some advantages of the hot-water bags are: They are soft and yielding. They can be changed or removed through a small opening. It is difficult to explain the mode of action of the hot-water bags placed in the abdominal cavity and within the stomach. It is not altogether clear whether this is due simply to the effect of heat acting directly upon the tissues, producing chemical changes, or to the physiologic increase in the circulation, or through nerve-influence acting upon both tissue-cells and circulation. Experiments seem to indicate that molecular chemical changes are produced—that the "side chains" in the albumin molecule are altered. Heat applied to the external surface does not result in the same effect produced by heat applied internally. [M.B.T.]

3.—Isaacson considers that after-pains are due to spicules sequestrums, tissue, mucus, food, or something else retained in the socket following tooth-extraction, and that local treatment and removal of the offending body are essential to relief. [D.L.E.]

1. Vaccination Eruptions. JACOB SOBEL.
2. Chronic Enteritis and Tuberculous Enteritis Treated with Hypodermic Injections of Arsenic. LOUIS KOLIPINSKI.
3. Anastomosis of Ureters with Intestine. REUBEN PETERSON.
4. School Break-Down. J. HENRY BARTLETT.
5. The Automobile in Country Practice. A. D. HARD.
6. Results of 200 Operations on Insane Women. R. M. BUCKE.

1.—Sobel describes a number of cases in which more or less generalized eruptions followed vaccination. These usually appeared between the ninth and fourteenth days, but the extreme limits were 5 days and 5 weeks. He records the following types: Erythematous, urticarial, papular, vesicular, pustular, erythema multiform, morbiliform, bullous or pemphigoid, and scarlatiniform. The proportion of children in which these eruptions occur was about 14%, 80 out of a total of 583. He records several cases of autoinoculation, and one in which a mother inoculated herself on the eyelid from her child. The most difficult differential diagnoses were those between the morbiliform type and measles. In these cases the onset was sudden, the rash disappeared early without desquamation, and Koplik's spots were not observed. In some cases resembling German measles, a differential diagnosis could not be made. An eruption, resembling that of chickenpox, was also observed, and in 2 cases the disease appeared in other members of the family. In conclusion, he mentions a number of sequels, the most common being deep ulceration in 67 cases. [J.S.]

2.—Kolipinski gives a brief description of the symptoms of **chronic enteritis**, which consists of alvine evacuations, occurring 3 or 4 times a day, especially just upon rising. Often there is a strong desire immediately after meals. The prognosis of this condition is unfavorable, spontaneous cure

never occurring, and if too long neglected some malignant complication is likely to arise. He reports 8 cases, selected from his notes, in which improvement or alleviation occurred. [J.S.]

3.—Peterson reviews the literature bearing on the subject of **ureterointestinal anastomosis** and gives the results of his own experiments and his deductions. Of 28 cases of ureterointestinal implantation in man, collected from literature, there was a primary mortality of 32%, and of the 19 who recovered from the operation, 2 died of pyelonephritis and 2 of uremia. Renal infection was responsible for the 9 fatal cases. Of 36 cases of ureterotrigonointestinal anastomosis collected there were 5 primary deaths and 2 more within 15 months. The author performed bilateral ureterointestinal anastomosis on 28 dogs, and 23 died from general peritonitis, from extravasated urine, and kidney infection. The last dog was dead at the end of 13 months. Lateral ureterointestinal anastomosis was performed on 16 dogs, 12 of which died; and ureterotrigonointestinal anastomosis was done on 19 dogs, 16 dying. Twelve of these died from peritonitis caused by sloughing of the flap. The author's conclusions are as follows: The best technic is that requiring the least amount of suturing of the ureters themselves. All efforts to prevent ascending renal infection in animals or in man when the ureter has been implanted without its vesical orifice have proved futile. It is impossible to determine in advance the extent of the infection which will result from ureterointestinal anastomosis. Hence the operation is unjustifiable, either for the purpose of making the patient more comfortable, as in exstrophy of the bladder, vesicovaginal or ureterovaginal fistula, or for malignant disease of the bladder. The results of ureterointestinal anastomosis through the formation of vesicorectal fistulas have not been favorable up to the present time. The success of Franck's experimental work in vesicorectal anastomosis justifies the expectation that the future results of this operation will be more satisfactory. The primary mortality of ureterotrigonointestinal anastomosis is low for an operation of this magnitude. While it cannot be denied that ascending renal infection may occur after this operation, the infection as a rule is of such a type that the chances of the individual's overcoming it are good. [A.B.C.]

4.—Bartlett in answer to an article in a popular journal claims that **school break-down** is not particularly common in this country. Many scholars are of course obliged to leave school as the result of ill health, but some studies and observations made by himself lead him to conclude that developmental defects are the most common cause. [J.S.]

5.—Hard discusses the various types of **automobile** in reference to their value to the country physician. The electric automobile is safe, easily operated, and is always ready to run. The storage batteries are very heavy; it requires frequent recharging, and climbs hills poorly. The hydrocarbon or gasoline engine is easily charged, carries enough fuel for 75 miles, and is always ready for use. It is heavy, gives off disagreeable odors, and easily gets out of order. The steam carriage is perhaps the most desirable. It requires special mechanical knowledge, frequently gets out of order, requires expensive repairs, and the fuel is apt to cause unpleasant odors. It is light, climbs heavy grades, develops speed readily, and is very easily controlled. Moreover, it runs 75 miles without renewing the fuel, and the latter can readily be obtained at any store. [J.S.]

6.—Bucke says they examined 256 women at the London asylum and found disease of uterus, ovaries or the adnexa in 219 cases. **Operation** was performed on 200 of these, resulting in 4 deaths. Of the 196 who recovered 83 were **cured of their insanity**, 45 others were improved, and the remaining 68 are unimproved up to date. Among the 63 cases operated on for causes not gynecological there was but 1 recovery from insanity. He further says the meaning of these facts seems to be that the diseased conditions under consideration, diseases of ovaries and tubes, have the most influence upon the mental health of the patient; that is, the most influence in the causation of insanity; that disease of the body of the uterus and cervix comes next in importance as a cause of mental disturbance; that uterine tumors and tears of the perineum rank still lower, and that ordinary surgical diseases, such as hernia and tumors of the body at large, seem to have no influence at all as causes of such

disturbance. No case was operated upon for insanity itself, but only when operation was indicated without reference to the mental condition. [A.B.C.]

2. The Progress of Medicine. HAROLD C. ERNST.

3. Acute Dilation of the Heart in Influenza of Children. F. FORCHHEIMER.

1.—Stedman contributes a collection of delightful personal reminiscences of the various prominent men connected with the Norfolk District Medical Society, whose characteristics have been described by a sympathetic and appreciative friend. [J.S.]

2.—Ernst, in an article on **Progress of Medicine**, first discusses the increase in the number of hospitals in the State of Massachusetts from the year 1850, when there were only 13, to the year 1900, when there are approximately 110. In addition, the improvement and enlargement of certain individual hospitals, such as the Massachusetts General, the Boston City Hospital, etc., have been very pronounced. He then mentions the changes that have taken place in the Harvard Medical School, the Faculty increasing from 8 to 34 in the half century, and the students and instructors in proportion. Also, the changes in the requirements for graduation in medicine and the possibilities for the future. He then speaks of the modifications in medical theories that have been produced by the discovery of the relation of bacteria to disease, and gives some hygienic principles that he deduces from individual peculiarities of the different bacilli, particularly mentioning the bacillus of typhoid fever and the bacillus of tuberculosis. Finally, he mentions improvement in diagnostic methods that have resulted from the clinical application of bacteriology. He claims to have been the first to feed infants with sterilized milk. In conclusion, he touches upon the serum-treatment of infectious diseases. [J.S.]

3.—Forchheimer reports a number of cases which have the common feature of **acute dilation of the heart** in the course of influenza. The symptoms are those of myocardial insufficiency, increase in the area of dulness, and development of murmurs best heard at the base of the heart. All these symptoms disappear under appropriate treatment. The dyspnea in these cases is usually extreme. In one case that he describes, the patient suddenly became blue in the face, and 2 hours later was found cyanosed, breathing rapidly, with a very weak pulse. He recovered under rest and treatment, but had subsequent attacks. In another case there was tachycardia, prolonged for a number of days. The temperature was high, and the pulse immediately after the attacks of coughing would become very rapid and almost imperceptible. Forchheimer discusses the cause of this condition, and after mentioning the theories of nervous influence and pulmonary congestion, expresses himself in favor of the former. [J.S.]

9.—A woman 6 months pregnant received a **gunshot wound** of the spine. She was shot in the abdomen with a 38 caliber revolver fired at close range; abortion followed the next day, and it was soon noticed that she had lost both sensation and motion in the lower extremities, and that there was retention of urine and feces. When seen 17 weeks after the injury she was becoming septicemic and the symptoms indicated that the bullet had pierced both walls of the stomach, had entered the spinal column and had either divided the cord or was interfering with its function by pressure. Five months after the injury laminectomy was performed, and on passing the finger along the anterior wall of the spinal column the conical point of the bullet could be felt projecting into the canal about one-third of its length; the other two-thirds was imbedded in the bed of the ninth dorsal vertebra. On each side of the bullet a spicule of bone projected into the canal. The dura and cord were held aside, the bullet extracted, the displaced pieces of bone removed; the theca was not sutured, but the muscles of the skin were drawn together by silkworm sutures and a strand of silkwormgut placed in the wound for drainage. Union was complete at the end of 18 days. One month after operation, the patient was placed in a permanent bath for treatment of bedsores, remaining 7 weeks, when she was greatly improved. Death resulted 9 months after the injury, probably from pyemia. Kramer deprecates the use of extension or counter-extension in cases of injury of the spine, advising operation as soon after injury as possible in order to avoid the occurrence of secondary conditions. In confirmation of his position he relates the case of a man whose spine was injured by a fall of 20 feet down a shaft. Laminectomy was performed 77 hours after the injury. The arches of the twelfth dorsal and first lumber vertebrae were removed. Six days after operation he passed urine and feces voluntarily. Three weeks after operation he was discharged and returned to his home, a portion of the way by sea. This patient's condition is still very good and he has been able to support himself and family as a cigarmaker. [M.B.T.]

10.—Eshner relates a case of **true angina pectoris** in a young man under 30 years of age and unattended with organic disease of the heart or vessels. He concludes, however, that it is not impossible that as a result of attacks of rheumatism of which the patient gave a history, insidious changes had been set up in the myocardium or the coronary arteries. 6. Extirpation of the Uterus, Vagina and Rectum for Carcinoma. WILLIAM M. POLK.

1.—Kelly describes 2 **new instruments**, one for making applications to the vaginal vault, and the other to facilitate the cleansing of the vagina. The first is a little glass reservoir with a tube which is inserted in the vagina; pressure is applied by compression of a rubber bulb, and the liquid or viscid materials contained in the reservoir are transmitted to the upper part of the vagina, where they are retained by a cotton or cotton-and-wool pack previously placed therein. The second instrument is a coneshaped vessel of hard rubber which is attached to the tube of the douche-bag and inserted

far enough to completely plug the vagina, thus causing the distention of its walls upon the flowing in of the cleansing fluid. After about a minute the nozzle is withdrawn and the fluid allowed to escape. This is repeated until a pint or more of fluid has been used. [W K.]

2.—Davis believes that the uterus should be douched when it is infected as shown by an abnormal lochial discharge, or a lack of the normal discharge with fever and rapid pulse. When the patient is profoundly depressed and has suffered from loss of blood, it is well to use normal salt solution rather than one of the carbolic derivatives. Mercurial solutions should not be used within the uterus. For exploring the uterus it is well to use a douche curet. This is preferable in septic cases to a sharp-edged instrument, as it is best to interfere as little as possible with the zone of resistance in the uterine tissue and with the thrombi closing its sinuses. Intrauterine douching may also be used in cases of postpartum hemorrhage and is most successful when followed by an intrauterine tampon of iodoform or sterile gauze. The two in combination empty the womb and make it impossible for a large clot again to form, while stimulating the uterus to contraction. [W K.]

3.—Weber pleads for a greater attention to surgical detail in obstetrical cases. He believes that all patients should be prepared as for a vaginal operation, the bedclothes and the patient's clothes freshly washed and put on clean for the confinement, the accoucheur and assistants in surgical attire and in a surgical state of cleanliness. When the child is about to be born, the patient should be put on a properly prepared table in the lithotomy position. Any necessary maneuver can be more dexterously performed on a table than in the bed. Forceps can be applied and used, and version and extraction more easily done. The perineum can be more readily protected, and after the birth of the child, hemorrhage, if any, can be more easily controlled. Besides, what is of greater importance, perfect aseptic and antiseptic work can be done only on the table. In every case an absolutely empty uterine cavity must be left. Large cervical tears should be sewed up immediately, small ones may be left in clean cases, but should be stitched where there is leukorrhea. The most careful search should be made for a laceration of the levator ani muscle or the floor of the pelvis. This is a most serious lesion if left untreated; for it can rarely be repaired later, as the torn fibers of the muscle retract and soon atrophy. Tears of the perineum should next be repaired. If the hand has been introduced into the uterus, if forceps have been used, if any suturing has been done, the whole genital canal should be copiously irrigated, with sterile water in the clean cases, and with lysol solution in the leukorrheal ones. The clean cases require no further local attention. The cases in which autoinfection is possible should have 2 copious antiseptic uterine irrigations daily for 3 or 4 days. [W K.]

4.—Noble believes ectopic pregnancy to be a relatively common condition. He is of the opinion that tubal abortion as compared with tubal rupture represents fully 75% of the cases. The violence of the hemorrhage depends partly upon the extent of the rent and the size of the vessels involved, and also whether the rent is more or less perfectly plugged by the partial escape of the ovum. In a general way, however, it may be said that the nearer the rent is to the uterus, the greater will be the hemorrhage. The following are the rules he uses to guide him in dealing with this condition: For cases of tubal abortion or rupture with hematocele, when the patient is in good condition, a deliberate operation is done, the appendage involved is removed, the mass of clots is removed with the hand, semiorganized clots are picked away except those parts which may be intimately adherent to the bowel or mesentery; then the pelvis is carefully sponged out with salt solution, the abdomen is left full of the solution and the wound closed. Should the opposite appendage require removal, hysterectomy is preferred to bilateral salpingo-oophorectomy, because it leaves the peritoneum of the pelvis in a more healthy condition. When the hematocele from a ruptured tubal pregnancy has suppurated, vaginal incision and drainage is the operation of choice. When there is shock and acute anemia from hemorrhage, a too refined operation is dangerous; the involved appendage should be rapidly secured and tied off; large masses of clots removed by the hand, and the abdomen washed out with an old-fashioned Tait irrigation, which will

remove the blood and wash out the clots with far less traumatism to the intestines than any other method. The abdomen should be left filled with the salt solution and rapidly closed. Noble reports two cases in which ectopic gestation occurred in each ovary successively. Both made uncomplicated recoveries. [W K.]

5.—Coe cites the reported cases of parasitic or migrant tumors of the uterus and ovary and adds some new cases to the list, the most interesting being that of a woman of 35, married 6 years, had 2 children, born respectively 4 and 2 years ago. During her first pregnancy a tumor could be plainly felt in the right iliac region, which was thought to be the head of a twin. After delivery it was recognized to be a pedunculated fibroid attached to the fundus of the uterus. Throughout her second pregnancy and after delivery the tumor occupied the same position and had not increased in size. Attacks of localized peritonitis and other symptoms making operation advisable, the tumor was found seemingly imbedded in the wall of the bladder with no trace of a pedicle at any point on the surface of the tumor, or at any point on the uterus. An interesting complication was a tubal abortion causing a mass in the Douglas pouch, surrounded by old and recent blood clots. The patient was discharged cured on the twenty-third day. Another case occurred in his service at Bellevue Hospital, in which a solid tumor was found in the vesico-uterine pouch, which was entirely independent of either the uterus or adnexa. This tumor contained a cheesy mass, in the center of which tubercle-bacilli were found, although no evidence of tuberculous disease could be found in the tubes and ovaries, which were removed. Whether this growth was originally attached to the uterus or not could not be determined. He draws the following conclusions: Subperitoneal fibroids may become detached from the uterus and may receive their nourishment entirely through adhesions. Such transplantation with entire disappearance of the pedicle must be exceedingly rare. Although axial rotation is probably the first step in the process, it is fair to assume that vascular adhesions form before separation is complete. Clinically, these tumors may be mistaken for growths developing primarily in the organ to which they attach themselves, especially ovarian, renal and splenic. Transplantation of ovarian and parovarian tumors is less common and is more likely to be followed by degenerative processes. Chronic rather than acute axial rotation is the usual cause. The clinical diagnosis of this condition is practically impossible. The prognosis is better in cases of solid than in those of cystic tumors. [W K.]

6.—Polk reports a case of extirpation of the uterus, vagina, and rectum for carcinoma. Obstinate vomiting came on and the patient died 82 hours after the operation. There was no peritonitis and no knuckle of intestine was involved, and Polk attributed death to the extensive area involved and the necessary irritation of important nerve-trunks, aided and abetted by the general condition of the patient which was mildly cachectic. [W.K.]

7. A Critical Summary of Recent Literature on the Localization, Diagnosis, Prognosis, and Treatment of Gonorrhea in Women. JOHN G. CLARK.

1.—Jung, in discussing diverticulums of the esophagus, mentions a method for differentiation between a diverticulum and dilation of the esophagus, which he considers an

addition to and an improvement upon Rumpel's method. Rumpel employs 2 tubes; one, with numerous perforations in its lower third, is passed directly into the stomach; the other into the esophagus above the cardia. Water, which is poured through the esophagus tube, will run down into the stomach through the perforated tube in case of a dilation. In the event of a diverticulum this will first be filled and only the overflow will run into the stomach. The contents of the diverticulum can be returned through the esophagus tube and accurately measured. The main condition of this test is that the perforated tube really enters the stomach. This, however, is often accomplished with great difficulty, especially in cases of large dilation. The author's method consists in introducing an ordinary stomach-tube, with about 10 small holes distributed over a length of about 30 cm. Into this tube a smaller one, which has only one hole at the end, is introduced. This double tube is capable of giving a double proof: (1) The stomach-contents may be aspirated by means of the inner tube and a test made for gastric juice; (2) the stomach can be filled and emptied at will. With these tubes still in position, the esophagus tube may be introduced, as in Rumpel's method, and the water-test be made. In case of dilation, the water will run through the perforation of the larger stomach-tube into the stomach, the inner tube being no obstacle, or it may be removed, the test for gastric juice having been made. In case of a diverticulum, a certain amount of water will remain in the pouch and can be returned through the esophagus tube. The author prefers a rather stiff stomach-tube and an inner tube 65 cm. long, on the order of a ureteral catheter. If the entrance to the stomach is difficult to find, the double tube, with the inner tube of soft metal, to which is given the curve of a Mercier's sound, is introduced. The author cites 2 cases in which his method was used. The first, a man of 64, who had always been healthy, but addicted to hasty eating, to the gulping down of large draughts of icewater, and intemperate smoking, complained of occasional intense cramps, pains in the region of the stomach, at which time a sense of suffocation supervened. This condition had continued for several years. For some time he has raised his food occasionally after eating, which diminished the sense of fullness in his stomach. He was not able to tell whether the food came from the esophagus or stomach, but always called it "vomiting." For 2 years he was almost unable to swallow, and lost flesh rapidly. A diagnosis of diverticulum of the esophagus was made which was confirmed by a skiagram. The treatment consisted of lavage of the esophagus, and semifluid diet, milk toast being a favorite. The spasms were cut short by the use of small **seidlitz powders**. The patient was made comparatively comfortable; he gained much in weight and was able to attend to his duties as policeman. The second case was a woman whose condition was similar to the case above. She commenced to suffer from violent cramps in the region of the stomach; later there was raising of food without nausea, large quantities of slimy water being brought up. Difficulty in swallowing and choking sensations supervened. A diverticulum of the esophagus was found. The treatment was much the same as in the above case. The author calls attention to the fact that the painful spasms may be overcome by the use of small seidlitz powders or effervescent bromo-water. [A.B.C.]

2.—Clemow gives some **clinical aspects of plague**. He says there are four varieties: Bubonic, pneumonic, septicemic, and the abdominal or enteric variety. As 80 to 90% of all cases are bubonic he discusses this variety only. The peculiarity of the plague **temperature-chart** is that it has no characteristic curve and is marked irregular. It usually rises more or less rapidly to 103° or 104°. In some cases it rises just before death as high as 106° to 108°. The mortality among 300 patients in whom the temperature rose 104° was 86%; among 202 patients in whom the temperature did not rise to 104° the mortality was 73.7%. A high temperature is a distinctly unfavorable sign. In discussing the condition of the alimentary system he says the appearance of the **tongue** varies much. Usually the dorsum is loaded with a white or grayish-white fur, its surface is dry and sometimes remarkably smooth, the tip and edges are usually clean, pink, and free from fur. In many severe cases the coating is thin, brown and glazed in appearance. The appearance of the tongue may undergo a very rapid change. **Vomit-**

ing, while not a characteristic sign, usually occurs as an early symptom and is probably of cerebral origin. The **bowels** are usually, although not invariably, constipated. This is probably due to a diminished activity of the intestinal glands. All gland structures in plague appear to have their secretory functions much diminished. This is particularly marked in the sweat-glands, kidneys, liver, and the salivary glands. Diarrhea, however, is not rare. The liver is occasionally slightly enlarged. Some degree of icteric tingeing of the conjunctivæ is common. The **nervous system** is almost from the first more or less profoundly affected; in this respect as in others, plague bears a striking analogy to typhus fever. It would seem that the plague toxins circulating in the blood have a specially intense action upon the entire nervous system. It is indicated by early headache, and giddiness; by extreme physical prostration, especially in the later stages; by mental phenomena such as apathy, delirium which may be of any degree, drowsiness, or coma, which are very rarely absent; by convulsive and paralytic symptoms which occasionally occur; by the mental changes which are sometimes left as one of the most unfortunate sequels of plague; and by trophic manifestations which are common accompaniments of this disease. Physical prostration and weakness is usually very marked and present in almost every case. The voice becomes weak and the muscles flaccid, and patients who at first show little signs of weakness or depression often suddenly become profoundly depressed. Convulsions are frequently present; they may be unilateral or bilateral, tonic or clonic. A convulsion may resemble in every respect an epileptic fit. Such patients rarely survive. **Risus sardonius** is common. Paralysis of muscular structures occurs; this appears to be, in part at least, the result of direct action of the circulating toxins upon the muscular fibers. The author has never seen paralysis of a group of muscles, paraplegia, hemiplegia, nor monoplegia, in this disease. This would indicate that the lesion is not in the cerebral cortex nor any part of the motor tracts. Some interference with speech is one of the commonest and most striking features of plague. Early in the disease, in the great majority of patients, slow, hesitating and peculiarly "thick" speech is characteristic. The reflexes in plague are almost invariably diminished or wholly lost. Nervous retention of urine is common. The organs of special sense, particularly the eye, are very apt to suffer. The degree of affection of the eyes may vary from a slight conjunctival injection to complete destruction of the eyeball. [A.B.C.]

3.—Cabot cites the case of a woman of 42 who sought treatment for what appeared to be an **aneurysm**. Over the region of the manubrium there was a pulsating tumor the size of a lemon, greenish black at the tip with a red areola around the black. A systolic murmur could be heard over the tumor. The author feared immediate rupture and the patient was hurried to the hospital ward. Rupture occurred 3 days later and instead of blood a puriform material escaped. It appeared that the swelling made its first appearance 7 years before, and in the course of a few months attained nearly its present size. The patient at that time was treated internally with potassium iodid and the tumor disappeared. The patient had a history of 7 miscarriages. There was no other suggestion of syphilis. The tumor had come and gone several times since its first appearance, generally yielding to potassium iodid treatment. There was no pain, dyspnea, dysphagia, cough, or other pressure symptoms. There was at this time in addition to the tumor already mentioned a second pulsating mass, larger, flatter, and less inflamed than the other. It was below the first named tumor and in the median line. A few days after the rupture of the higher mass, the lower one was opened without ether and purulent material likewise escaped. Within a month the tumors had almost entirely disappeared, but a sinus remained into which a probe could be passed entirely through the sternum and to some distance downward behind it. The sinus persisted and it was thought there was no aneurysm present. She complained 3 months after applying for treatment of a sound in the thorax like water dropping on a tin roof. The husband said that this sound could sometimes be heard at a distance of 12 feet. Her general health seemed good. At midnight she got up for a drink of water. The husband heard a scream and a gushing sound. She fell dead in a pool of blood. The aneurysm, for such it proved to be,

had ruptured. Whether the process going on in the sternum may have been partly gummatous and partly due to pressure of the aneurysm, and exactly what was the purulent material, the author does not know. He is of opinion that a changing condition in the clot inside the sac caused the varying conditions of the aneurysmal tumor. [A.B.C.]

4.—Ravenel, on account of the recent agitation against vaccination, attempted to produce **syphilis in calves by inoculation from man**. He gives a brief review of other experiments along this line. Two calves were selected, a heifer about 8 months old, and a bull about 14 months old, both in good condition, though the heifer was known to be tuberculous. The area selected was shaved, washed thoroughly, and rinsed with sterile water, after which the surface was scraped until a bloody serum began to exude. It was next scarified, and into this the syphilitic material was rubbed for not less than 5 minutes. A second scarification was then done. The heifer was inoculated in two places and the bull in one. The syphilitic material was obtained from a patient in the secondary stage. In neither animal did syphilis develop. The heifer was killed 54 days and the bull 103 days after inoculation. A microscopic examination of the central and peripheral nervous system was made in each case. In neither case was any evidence of syphilis found. [A.B.C.]

6.—Duel advocates **electrolysis** in the treatment of chronic tubal catarrh and chronic catarrhal otitis media. While it is possible that a chronic aural catarrh may begin in the tympanum, with no very marked evidence of nasopharyngeal or tubal catarrh, it is usually the case that the tubal catarrh precedes or accompanies the tympanic inflammation. **Chronic tubal catarrh and chronic otitis media** suggest only a difference in position of the inflammation and not in its character. Where the affection is confined to the tube the impairment of the hearing is functional, and is restored so soon as the normal patency of the tube is effected. Tubal obstruction is present early in a large percentage of all cases of chronic hypertrophic catarrhal otitis media. It is our duty whenever there is a stenosis of the eustachian tube to remove the obstruction as rapidly as possible. In every instance when the obstruction is due to an organized exudate the best method for its removal is by electrolysis, for the following reasons: It is more rapid, more efficient, and the results are more permanent. The electrolytic bougie may be easily passed through strictures which are so firmly organized that it is impossible to pass a cotton bougie. A stricture once removed by this method is permanently removed. The removal of obstructions in the tube is only a large factor in but not the whole treatment of these conditions. The prognosis depends largely on the amount of injury to the tympanic structure. The narrow tube should be opened in every instance. [A.B.C.]

7.—Clark says that **gonorrhea in women** almost always begins in the urethra. The extension of the inflammation upward is rapid. As a rule, the symptoms are slight and fleeting in character. He quotes Bumm as saying that within 6 to 10 weeks from the appearance of an acute attack the process has entirely healed itself. The tendency is to a complete healing, but there are cases which become chronic despite all treatment, and persist for years. The symptoms in such cases are usually obscure and easily overlooked, but yet sufficiently active to transmit the infection. Gonorrheal inflammation of the epidermal surfaces of the external genitals is always a secondary affection and is not specific in character, but is of an eczematous nature. Unless absolute cleanliness of the parts is maintained, superficial ulcers and even condylomas frequently form. These latter are often attributed by the inexperienced observer to syphilis. True gonorrheal inflammation of the vagina is of rare occurrence compared with that of the urethra and cervix; this is because its epithelium is stratified and it has no glands. Inflammation of the cervix in point of frequency is next to the urethra. Cervical gonorrhea is especially prone to become chronic. In many cases the affection is limited to the cervix, and does not tend to pass the internal os. When it does, however, a general fundal endometritis occurs. There is then constant danger of the disease passing into the fallopian tubes and forming an acute salpingitis which becomes more or less chronic, and finally terminates in pyosalpinx. The diagnosis of gonorrhea in women is much more difficult than in men, because of the leukorrheal discharge which is more

or less normal in women. The certain diagnosis depends very largely upon the demonstration of the gonococcus in the secretions. Great care should be exercised in securing pus for examination, that it may not be contaminated by other organisms. For clinical purposes methylene-blue solution is a practical and easily manipulated staining fluid. To make the diagnosis certain the gonococci must be found inside of the pus-cells. Although the results of gonorrheal infection in women is usually most serious, yet it must not be forgotten that a considerable proportion of cases run a simple, mild course. In women, so far as the question of prognosis is concerned, the localization of the pathologic process is the deciding feature. If the case is acute and limited to the urethra and cervix, prognosis is favorable. If the infection gains access to the uterus and becomes chronic, the prognosis as to complete cure is doubtful. Should the disease pass to the tubes the prognosis is still more unfavorable. Concerning the **treatment** of this infection there are two opposing views, one holding that absolutely nothing should be done in the way of local therapeutics with the view to the self-limitation and self-healing of this disease, while the other insists that active germicidal remedies are indicated from the very onset. The author is of opinion that cleanliness is the first desideratum, and in the majority of cases is the only measure upon which stress should be laid. After 4 to 6 weeks, when the subacute stage is reached, Bumm insists upon local applications; and according to this author the remedies which are based on bacteriologic experiment for their inhibiting effect are absolutely worthless in the treatment of subacute and chronic cases. The author strongly recommends ichthyol in the treatment of gonorrhea. Silver nitrate solution is also recommended. Absolute rest in bed during the acute infection is one of the chief points in treatment. Operation for pyosalpinx may become necessary, and when such is done the author believes in leaving the ovaries and uterus. [A.B.C.]

5.—Rosenwasser suggests that the condition in some cases of **vaginal discharge in children** is caused by an attenuated or not fully developed gonococcus that does not react to Grams' stain. The normal vagina with its bacterial flora, under certain conditions not yet understood, seems to be particularly susceptible, especially in hospital wards, to develop a discharge in which **diplococci** are found which, both in stain and cultural characteristics, cannot be differentiated from the gonococcus. The consensus of opinion seems to be that the cases are cases of true gonorrhea. The infection usually attacks the vagina because the mucous membrane of that canal is more susceptible than the conjunctiva, for example, the granular matter found in the pus in these cases may be the remains of the gonococcus. [A.M.S.]

7.—The case of a boy of 17 is reported. He was admitted to the hospital with a very severe cachectic form of syphilis which he had contracted 4 months previously. He had been treated with mercurial pills and black wash. In spite of vigorous treatment his condition gradually became worse; large serpiginous ulcers formed and the patient became extremely emaciated; paraplegia developed, he had attacks of dyspnea with some cough, and he died after a succession of convulsive attacks. No necropsy was obtained, but the cause of death is attributed to cerebral syphilis. The case is reported as one of those unusual attacks of syphilis which proceed rapidly to a fatal termination in spite of the vigorous treatment. [M.B.T.]

The Journal of Mental and Nervous Diseases.

July, 1900. [Vol. 27, No. 7.]

1. A Case of Wernicke's Conduction Aphasia with Autopsy. HOWELL T. PERSHING.
2. A Clinical Study of Some Reflexes. JOSEPH FRAENKEL and JOSEPH COLLINS.
3. A Digest of Recent Work on Epilepsy. L. PIERCE CLARK.

1.—Pershing reports a case of aphasia that presented not only a curious symptomatology, but an unusual localization. The patient, a man of 45 years, had become unconscious while driving, and had fallen into the bed of a small stream where he lay for about 36 hours. There was hemiplegia of the right side. In about a week the patient returned to consciousness, but exhibited complete paraphasia, that is to say, his talk was a mere jargon. The paralysis disappeared. Some weeks later he apparently understood any question that was asked him and would make an energetic attempt to answer it, but his talk was never intelligible. He could write his own name, but nothing else. When he attempted to read aloud, he would pronounce a few of the words correctly and would approximate the pronunciation of some others, but the majority were not pronounced at all. Two months after his first attack he had a second, during which he died. A spot of softening was found in the left hemisphere just above the fissure of Sylvius, and 6 cm. back of the vertical branch. This was situated where, according to the latest anatomical authorities, it might interrupt communication between the first temporal and third frontal convolutions; that is, between the sensory and motor areas for voluntary speech. The author regards this as perhaps the most typical instance hitherto recorded of true conduction aphasia. It seems to substantiate very thoroughly the theoretical deductions of Wernicke in regard to this type. [J.S.]

2.—Fraenkel and Collins examined 290 cases with Musken's tonometer, an instrument that is said to measure the tonicity of the Achilles tendon. Sixteen measurements were made on each foot and the average of the 32 regarded as the mean of the muscular tone. In addition they determined the tension of the patellar tendon by palpation. The kneejerk under various conditions and positions, the Achilles jerk and plantar reflexes and finally the mechanical irritability of the quadriceps muscle. They divide their cases into 3 groups according as the muscle tone falls within the limits of—12, 12 to 17, and 17 to 27; characterized respectively as hypertonus, physiological tonus, and hypotonus. In the cases of hypotonus, the kneejerk was absent in 16—14 of tabes, 1 of Friedreich's ataxia, and 1 of peripheral neuritis, and it was diminished in 15 cases. In 20 cases it appeared to be normal. Among the hypertonic cases, 22 had absent or diminished reflexes. In all the others they were normal or exaggerated. Of these 22 cases, 7 were tabetic. In others, here were local reasons such as edema, tremor, clonus, or something of that kind which interfered with the estimation. In 2 cases it was impossible to explain why the condition occurred. In the group of physiological tonus, the kneejerks

were either slightly lessened or normal. The authors, therefore, conclude that tendon reflexes are complex phenomena; their existence depends upon the nutrition and reaction of the muscle, and upon the state of the reflex arc. The plantar reflex according to them is always present unless there is a manifest and adequate cause. It is diminished in neurasthenia. It is usually delayed in tabes, sometimes for as much as a minute, and may not be entirely absent when total anesthesia and total motor paralysis are present. Babinsky's reflex was studied with especial care and the order of events appears to be, first, slight contraction of the quadriceps, then flexion of the four toes, plantar flexion of the foot, and dorsi-flexion of the big toe with other movements in the limb. They confirm the results of Babinsky that his reflex is not found in normal individuals, and is only found when the pyramidal tracts are diseased. The kneejerk often presents curious abnormalities if it is too frequently tested in a short period of time. [J.S.]

Wiener klinische Wochenschrift.

1. My Results from Operation for Rectal Carcinoma. JULIUS HOCHENEGG.
2. The Technic of Wedge-Shaped Osteotomy of the Tibia. LEW LUKSCH.
3. The Effects of Hereditary Syphilis. E. FINGER.

1. Hochenegg reports 121 operations for resection of the rectum by the sacral route. He has also performed 50 other sacral operations, making a total of 171, with only 18 deaths. The patients usually recover, and are able to get about without pain or any unfavorable results. He prefers to operate without previous irrigation, as it is impossible to cleanse the rectum thoroughly, and thickened feces are less trouble during the operation than the fluid feces. He generally finds it necessary to open the peritoneum, but has had only 1 unfavorable result. In this case the peritoneal suture was ruptured by vomiting during recovery from the anesthetic. If the anal portion is diseased he sutures the intestine immediately below the sacrum. Incontinence of feces may be avoided by wearing a sponge held in place by a firm rubber band. This is as satisfactory as any method of preventing incontinence of feces. He has practised Gerstung's method with unfavorable results in several cases. As to the permanent results of the operation he has been able to obtain reports of the later condition in 62 cases. Ten patients died and in 22 it was impossible to get information. Counting these patients as dead and estimating as cured patients which have remained well over 3 years he finds that the percentage of recoveries should be 25%. [M.B.T.]

2.—Luksch believes that a fault of the Meyer Schede's method of performing osteotomy is that a wedge of bone is removed from the tibia alone. He advocates removal of a wedge of bone also from the fibula, taking a prism-shaped section from the tibia and a wedge-shaped piece from the fibula. This operation is indicated only in cases in which the bend is located below the knee and probably only in cases in which there is great deformity. [M.B.T.]

May 10, 1900. [13. Jahrg., No. 19.]

1. Endemic and Sporadic Cretinism and Its Treatment. WAGNER V. JAUREGG.
2. A Case of Cerebral Paralysis in a Child with Remittent Paralysis. EDUARD MENZ.
3. The Bacteria of the Urethra. SCHENK and AUSTERLITZ.

1.—A very masterful discussion of the subject of cretinism of the sporadic and the endemic type, which the author believes are both dependent upon morbid conditions or absence of the thyroid gland. He is also of the opinion that several other conditions affecting the skeletal growth, as, for example, chondrodystrophia, are dependent upon thyroid disease. The marked success of thyroid treatment in sporadic cretinism warrants its systematic employment in the endemic form. [D.R.]

2.—Menz reports a case of infantile cerebral palsy with crossed abductus paralysis in a girl of 10 years. The palsy occurred without any apparent cause when the child was 6 months old. Menz places the lesion in the pons. [D.R.]

1. Psychic Derangements of Defecation. A. PICK.
2. Resuscitation from Suffocation, Chloroform Poisoning and Electric Shock. J. PRUS.
3. The Technic of Alexander's Operation. GUIDO TÖRÖK.

1.—Pick reports a case in which in a neurasthenic individual **defecation** was interfered with in a manner analogous to a condition of urination called by Paget urinary stammering. It was impossible for the man to perform the act of defecation in the presence of any one else or even when he believed that some one was in an adjoining room. He was in the habit of reading combinations of lottery numbers in order to abstract his attention from the act of defecation. Micturition was similarly affected. [D.R.]

3.—Torox mentions some of the modifications of **Alexander's operation** and states that in all methods the subcutaneous joining or knotting together of both round ligaments above the symphysis, according to Gardener, promises the strongest guarantee against a return of the malposition. He describes in detail the operation as thus performed upon a bedridden patient, aged 19, with most favorable results, as she left the hospital well and able to resume her customary labor. The simple stitching of the round ligaments to the layers of the inguinal canal may be sufficient in many cases; but when the abdominal walls are flabby or relaxed, it forms a small security against relapse. Then Gardener's modification is to be preferred, since it furnishes a point of support for the united ligaments, and also the strain upon the ligaments is exerted not sidewise but lengthwise. This method, however, can only be used when the operator can freely prepare sufficiently long and strong pieces of ligament. Of course in all cases care must be taken so to close the inguinal incisions with the Bassini stitch as to effectually prevent any subsequent hernia. [W.K.]

1. The Present Position of the Wound-Question in War, and Its Correlation to Sanitary Service in the Field. J. HEBART.
2. So-called Syphilis Hereditaria Tarda among the Troops of the Vienna Garrison. F. SCHUSTER.
3. Resuscitation from Suffocation, Chloroform-Poisoning, and Electric Shock. J. PRUS.

1.—From a thorough study of **gunshot injuries**, Hebart draws the following conclusions: The new repeating rifles and new forms of artillery cause greater loss of life than the older weapons. The percentage of deaths is about 25; of severe injuries, about 20%; and of slight injuries, about 55%. The wound by the small-caliber bullets are more favorable than those inflicted by the older form of weapon, and less frequently call for extensive surgical intervention. Not only the first dressing, but the means of transportation are matters of importance in the result. Trained ambulance-men are needed, and sufficient medical aid to attend to severe emergencies. The preparation of first-aid packages and bandages are of considerable help. It is of decided advantage to have field hospitals located as near to the field of action as possible, as it saves carrying the patients so far. Inasmuch as the operative work is often necessary during the night, the method of lighting is of considerable importance. Magnesium torches and acetylene gaslights are suggested. Since the Franco-Prussian war the South-African campaign is the first in which there has been greater loss of life from wounds than from disease. This is partly due to the effectiveness of the small caliber bullets, and partly to the more efficient sanitary and administrative measures. [M.B.T.]

2.—Schuster, during 3 years, observed 51 cases of apparent late **hereditary syphilis** among recruits from Bosnia and Herzegovina. In none of the cases was it possible to prove the existence of a primary lesion. Nevertheless, the author is of opinion that the cases were not examples of syphilis hereditaria tarda, but of **acquired syphilis**, the primary lesion having been acquired early in life through accident. [D.R.]

3.—Prus has carried out an extensive series of experiments on animals to determine the best methods of **resuscitation** after apparent death from asphyxia, chloroform poisoning, and electric shock. He advises opening the thorax,

and practising direct massage of the heart, and performing tracheotomy with direct introduction of air into the lungs. He believes that resuscitation is possible by this method in patients who have been dead apparently for over an hour. He has practised this method once on a man who attempted suicide by hanging. On opening the pericardium, there was not the slightest trace of motion of the heart. Massage was begun at once, and tracheotomy was performed, and air introduced into the lung by a bellows. After 15 minutes, the first trace of rhythmic contraction of the heart was noticed, and continuing this method of treatment, recovery resulted. [M.B.T.]

May 31, 1900. [13. Jahrg., No. 22.]

1. The Knowledge of the Agglutinating Capacity of the Human Blood Serum. JULIUS DONATH.
2. Cholechootomy and Cholecystenteroanastomosis. FRITZ Pendl.

1.—Donath has investigated the **agglutinating action of human blood-serum on human blood-corpuscles**. He found that the serum from the majority of cases of chlorosis had an agglutinating action upon his own blood. Among secondary anemias 7 out of 20 had agglutinating action. One case of leukemia also agglutinated his blood very markedly; while the serum from a case of pernicious anemia did not. [D.R.]

2.—A man of 29 had been suffering for 7 weeks with attacks of severe abdominal pain with more or less fever, occasional chills and jaundice. The urine was dark colored and stools clay colored. For about 4 years he occasionally had attacks of abdominal pain and vomiting, the pain being especially severe under right border at the ribs. When transferred to the surgical department of the hospital it was possible to feel gallstones through the abdominal wall. An incision was made through the rectus muscle and on opening the abdomen a movable stone was found about 1 cm. above the opening of the common duct into the duodenum. There was also a stone just behind Vater's papilla; the stones were removed through a longitudinal incision. Another stone was removed from the hepatic duct, and in all 22 stones were removed from the ducts and gallbladder. A soft catheter was inserted into the common duct and carried out through the abdominal wound. The opening in the gallbladder was sutured to the parietal peritoneum. After biliary fistulas had existed for about 2 months an operation was undertaken to close them, after which the patient suffered from symptoms of recurrence of the attack. At another operation it was found that the intestinal end of the common duct had become a thick and impervious strand of connective tissue. **Cholecystenterostomy** was performed and 3 months after the operation the patient was in perfect health. In a second case a man of 54 had been suffering with symptoms of biliary obstruction. A tumor was felt in the region of the gallbladder. On operation the gallbladder and ducts were found entirely free from stones, but in the region of the duodenum there was a nodular slightly movable tumor the size of the fist which proved to be carcinoma of the pancreas. Cholecystenterostomy was performed with the aid of Murphy's button. An uneventful recovery followed, and the button was passed 14 days after the operation. All signs of biliary obstruction disappeared. [M.B.T.]

Berliner klinische Wochenschrift.

May 7, 1900. [37. Jahrg., No. 19.]

1. The Treatment of Infected Wounds with Hydrogen Dioxid. v. BRUNS.
2. The Secretion of Acids in the Stomach. S. TALMA.
3. Chronic Fibrinous Bronchitis. H. STRAUSS.
4. Resection of the Rectum. WILLIAM LEVY.
5. The Demonstration of Bone Structures by Röntgen Ray Pictures. JULIUS WOLFF.

1.—von Bruns recommends **hydrogen dioxid** in the treatment of infected wounds. The favorable results depend not upon the bactericidal effect, for a series of experiment proved that it is without any such action. It is probably due to the action of the oxygen on anaerobic bacteria to some extent and more upon the mechanical action of the foam

of the dioxid, forcing out of the wounds, secretions, blood-clots and necrotic tissue and in this way cleansing it. He uses the dioxid in irrigation, with moist tampons. [M B T]

2.—For the purpose of determining the acid secretion of the stomach Talma prefers Liebig's meat extract. He introduces, in the morning, into the empty stomach that has been thoroughly washed, an accurately neutralized solution of 2 grams of Liebig's meat extract in one liter of water, at the temperature of the body. The solution is introduced with the stomach-tube and is evacuated at the end of an hour. The acidity is readily determined, phenolphthalein being used as an indicator. The Liebig solution contains either very little or no albumin, therefore does not neutralize any of the acid, and the determinations are easy. [D R]

3.—Strauss reports a case of chronic fibrinous bronchitis in a man of 58. The disease resisted all treatment and subsided only after the patient had passed through an attack of influenza; but even after that the sputum still contained Charcot-Leyden crystals, but without the presence of fibrinous coagula which had been found in abundance during the attacks. The coagula gave the fibrin reaction. The Charcot-Leyden crystals also staining blue with the fibrin stain; and Strauss concludes that there is no reason to believe that the crystals are of a mucoid nature, but that the basal substance contains a body which takes the stains characteristic of albumins. In the coagula diplococci resembling the pneumococcus were found. The leukocytes present were of the mononuclear variety. There were in the patient at no time any attacks resembling bronchial asthma.

4.—Levy reports the case of a woman of 45, who had suffered for several months from the usual symptoms of carcinoma of the lower bowel. The operation of resection was undertaken by the method usually known as Schlange's. A convex incision was made with its concavity toward the coccyx; the bone was exposed and the sacrum was divided at the level of the lower border of the fourth sacral foramen. The bone was drawn down with a sharp hook, the diseased intestine was isolated and resected and the ends were united by continuous suture in two stages. The sacral wound was then tamponed with iodoform gauze. A good recovery followed. Levy claims to have been the first to advise this method of operation. [M B T]

2. The Origin of Excretion of Oxalic Acid. E. SALKOWSKI.
3. The Value of Bronchoscopy in Carcinoma of the Lungs. GUSTAV KILLIAN.
4. The Reflexes of the Nasal Mucous Membrane in Relation to Anesthesia. FRANZ BRUCK.

1.—Martius emphasizes the constitutional element in disease. [D R]

2.—It has long been a question whether oxalic acid in the urine comes from metabolism or is merely that which has been introduced in the food. Salkowski is of the opinion that oxalic acid may, in man, be a metabolic product. Its source, however, is not the albumins; it is in some way connected with uric acid, and is, like the latter, probably a derivative of nuclein. Its seat of formation is in all probability the liver. The amount excreted varies with the individual. Persons who have a tendency to oxalic acid stone-formation should avoid food rich in nuclein and such foods as contain oxalic acid. [D R]

4.—Bruck calls attention to Rosenberg's studies of syncope during chloroform-anesthesia. These unfavorable results were supposed to be caused by reflex irritation of the heart and respiratory center in the medulla from irritation of the peripheral endings of the trigeminus in the nasal mucous membrane, and Rosenberg attempted to overcome this irritation by cocaineization of the nasal mucous membrane. Bruck finds by experiment that complete cocaineization of the entire mucous membrane of the nose is impossible and he states that if it is found after further experimentation that it is necessary to prevent this nasal reflex because of the danger to life in chloroform-anesthesia that it will be necessary to shut off the entire nasal cavity. [M B T.]

1. The Hetal Treatment. C. A. EWALD.

2. Hemolysin. P. EHRLICH and J. MORGENROTH.

3. Influenza and Chronic Heart-disease. SCHOTT.

4. Are Special Divisions for the Tuberculous Necessary in Hospitals. E. ARON.

1.—Hetol (zimmtsaures natron, sodium cinnamate) has been recommended by Landerer for the treatment of phthisis. It is given by intravenous injection, beginning with doses of 1 mgm. every other day, and gradually increasing the dose until 16 mgm. are given. Ewald has used it in a series of 25 cases, and has come to the conclusion that it has not the beneficial effects claimed for it by Landerer and others, but that as there are no deleterious effects, further tests with it are justifiable. [D R]

2.—The introduction of the red corpuscles of one species of animal into the body of an animal of another species produces in the latter a substance called hemolysin, capable of dissolving the red corpuscles of the animal species from which the blood was derived. This hemolytic action is exercised not only in the body, but also *in vitro*, and is connected with the existence in the hemolytic serum of two bodies; one, called the *immunkörper*, the other, the *competent or adiment*. The *immunkörper* has a specific affinity for the corpuscles of the other animal species and, in addition, for the adiment, a body of a ferment-like character normally present in the serum. By reason of these two affinities the *immunkörper* acts as an intermediate body and enables the complement to dissolve the red corpuscles. The formation of bodies analogous to the *immunkörper* is a widespread function, and occurs after the injection of leukocytes, ciliated epithelium, renal epithelium, spermatozoa, etc. The injection of any one of these into an animal of another species brings about the development in the serum of substances capable of dissolving the particular cells in question. These facts are satisfactorily explained by the lateral chain theory of Ehrlich. They are probably of great significance in pathology and have a bearing upon those changes which follow the absorption of cells in the body. If large hemorrhages are absorbed, if there is an acute atrophy of an organ, if lymphatic tumors melt down under arsenic, or if a goiter subsides, the conditions are given for the development of reactive substances in the individual's own body. It is important to determine whether the absorption of such material in the body itself is capable of producing reactive changes. It is *a priori* unreasonable to suppose that since the injection of blood-corpuscles from another species of animal produces a hemolysin, the injection of blood from the same animal or the absorption of blood from a cavity gives rise to a hemolytic body; if it did, the red corpuscles could be dissolved. In order to get an insight into these questions, the authors injected goats with the blood of other goats. One animal (goat A.) received blood mixed from three other goats (1, 2 and 3). Its blood-serum very soon became strongly hemolytic for the blood of goats 1, 2, 4, 5, 6, and 9. Goats 3 and 8 showed a lesser sensitiveness to the serum, while goat 7 showed very little. If a drop of the blood of goat A was mixed with its own serum *in vitro*, no solution whatever occurred. The authors designate the hemolysin developed by the injection of blood from the same species of animal as *isolysin*; that produced by the injection of blood from another species, as *heterolysin*. The *isolysin* is not, however, an *autolysin*, *i. e.*, a lysin which dissolves the corpuscles of the animal in the serum of which it circulates. The fact that the *isolysin* is not an *autolysin* may be explained on the ground that the corpuscles of the same animal lack the lateral chain which binds the hemolytic *immunkörper* circulating in its own serum. These lateral binding chains Ehrlich calls *receptors*. The hemolysin of normal dogs' and goats' blood injected into other animals produces *antihemolysin*, *i. e.*, a substance which prevents the solving action. This was also found to occur when the *isolysin* from goat A was injected into other goats; the serum of such other goats became *antihemolytic*, and when mixed with the *isolysin* from goat A destroyed the solving action of the latter upon goats' blood. The *isolysins* produced in different goats by the injection of serum obtained from another goat, differed in their hemolytic properties, showing that the individual reaction of the animal played a part in the production of the *isolysin*. Thus, the *isolysins* developed in goats A, B, and C, by the injection into each of goat serum (from the same goat) dissolved not only goats'

blood-corpuscles, but also those of sheep. The isolysin of goat D, on the other hand, did not dissolve the corpuscles of sheep. The effects of the injection of blood serum from the same species of animal will depend upon various factors. It must be assumed that the injected red corpuscles have several lateral chains capable of uniting with suitable receptors in the body. If these receptors do not exist in the body into which the corpuscles are injected, there is no reaction whatever; no hemolysins are formed. If the receptors exist a hemolysin will be produced, because the lateral chain in the red corpuscles unites with the receptor in the animal's body, and the latter is reproduced in excess, is thrown into the blood, and constitutes the isolysin. There is also a third possibility, viz., the production of antiautolysin, which need not be further discussed. One interesting conclusion drawn by the authors from these complicated facts is that it is wrong to infer because blood-serum, secretions, and excretion from the human body in disease are toxic for animals, that they are also toxic for the organism of the patient. If, for instance, the serum of a scarlet-fever patient is toxic for guinea-pigs, it may, nevertheless, be perfectly harmless for man, especially for the patient himself; and if the serum from an anemic patient dissolves the corpuscles of other individuals, it does not follow that this explains the production of the anemia. It is probable that the hemolysin is an isolysin and not an autolysin. [D.R.]

4.—Aron does not think that it is necessary to isolate phthisical patients in general hospitals in separate wards. In his opinion the danger of transmission to other patients is small, and the depressing influence of the association of patients with the same disease is very great. [We cannot agree with these views, and are decidedly of the opinion that phthisical patients should be separated from the others. We should consider the adoption of Aron's plan a backward step. D.R.]

1. The Insane Criminal. E. SIEMERLING.
2. Congenital Deficiency. O. HUEBNER.
3. Irritation Experiments on the Spinal Cord after Decapitation. A. HOCHÉ.
4. Observations on the Treatment of Gonorrhea. LEOPOLD CASPER.
5. Influenza and Chronic Heart Disease. SCHOTT.

1.—It has come to be recognized that there is no single act which in itself proves insanity on the part of the doer—that an expert investigation includes an examination of the entire individual in corporeal and psychical respects. The insane, experience has taught, violate the laws more frequently than healthy persons. Many of the insane are wrongly placed in prison because of the widespread belief that simulation is practised. This prejudice concerning simulation causes a failure to recognize the peculiarities of the mental disturbance. Moreover, simulation and insanity do not exclude each other. The study of degeneration and its relation to the psychoses has not as yet yielded very satisfactory results. The question of caring for the insane criminal is an important one. Three systems have been developed: a special institution, a special division of the prison, and the ordinary asylum or a special division of it. The erection of special divisions in large prisons is probably the best solution of the problem, so long, at least, as the insane criminal is serving his sentence. An important point demanding attention is the better education of prison physicians. Lombroso's studies are interesting, but they do not justify the identification of criminality and insanity. It is the duty of psychiatry to secure more element consideration of the mentally deficient before the courts, so that the punishment may correspond to the defective mental development. [D.R.]

2.—Huebner reports a case of congenital absence of some of the nuclei of the ocular, facial, and hypoglossal nerves in a child of 1½ years. There was a bilateral external ophthalmoplegia and bilateral facial and hypoglossal paralysis. There was also a total absence of tear secretion. The child died of an intercurrent attack of measles with pleuropneumonia, and the autopsy showed absence of the left hypoglossal, left facial, and of both abducens nuclei, while the right hypoglossal and the right facial nuclei were far less rich in

cells than normal nuclei. The left posterior longitudinal bundle was also absent. Huebner believes that the condition (the so-called infantile Kernschwund of Möbius) is dependent rather upon aphasia or hypoplasia than upon inflammatory degenerative processes. [D.R.]

3.—The author has had the opportunity of examining the bodies of 2 persons that had been beheaded. He found that the spinal cord was irritable for several minutes after decapitation. He believes that the electric stimulus does not act directly upon the long motor pathways, but reflexly through the medium of the sensory fibers. [D.R.]

4.—The author pleads for a conservative treatment of gonorrhea. [D.R.]

5.—Schott points out the disastrous effects which the recent epidemic of influenza had upon the heart, especially in cases with previously existing cardiac disease. [D.R.]

1. Typhoid Fever. RUMPF.
2. The Value of Alcohol as a Disinfectant. SALZWEDEL and ELSNER.
3. Conception of the Term "Gastric Dilation" in the German Literature since 1875. ARTHUR HESSE.
4. Estimating the Strength of Heart Sounds as a Help in Diagnosis. HEIN. BOCK.
5. Influenza and Chronic Heart Disease. SCHOTT.

2.—Alcohol in proper dilution is a very efficient disinfectant, its disinfecting properties depending partly upon its desiccating action and partly upon a distinct toxic influence upon the bacteria. In efficiency it may be classed between corrosive sublimate and carbolic acid. The best solution for the disinfection of the hands is slightly acidulated 80% alcohol. [D.R.]

4.—Bock describes an instrument devised by himself and the late Oertel for the determination of the strength of the heart-sounds. [D.R.]

5.—Von Vogl in an appendix to Schott's article discusses influenza and its effect upon the heart in the army. He found, as did a number of observers in this country, that one of the marked symptoms during convalescence from influenza was bradycardia. [D.R.]

Münchener medizinische Wochenschrift.

June 12, 1900. [47. Jahrg., No. 24.]

1. The Present Position of our Knowledge of Tuberculosis, Especially Pulmonary Tuberculosis. A. TREUPEL.
2. A New Test for Urine and Sugar. EDLEFSEN.
3. The Therapy of Cholelithiasis. HEINRICH SCHEUER.
4. Ascending Traumatic Neuritis, without an External Wound. K. BRODMANN.

6. The Dangers of Vaginal Irrigation. A. THEILHABER.
7. The Individual Signs of Pregnancy, Including Remarks upon the Anatomical Condition of the External Orifice of the Urethra. O. NÄGELI.
8. The Operative Treatment of Ulcer of Stomach and Duodenum. F. KIEFER.

1.—An interesting resume, with a wealth of literary references, concerning the present status of our knowledge of tuberculosis—particularly pulmonary tuberculosis. One point of interest which might be quoted is the author's objection to respiratory gymnastics, especially deep inspiration, in recent cases of tuberculosis. [D.R.]

2.—Edlefsen speaks of a new test for sugar dependent upon the use of permanganate of potassium, but does not clearly describe it. [D.R.]

3.—Scheuer has analyzed the cases of cholelithiasis treated in the St. Hedwig Hospital at Berlin during 10 years. Of these cases 89 were treated in the medical and 43 in the surgical wards. He followed up the cases as well as he could, and was able to trace 57 of the medically treated. He found that after from 1 to 2 years 13 patients still suffered; after from 3 to 4 years, 5; and after from 5 to 8 years, 5. Twenty-two, or 41.5%, were cured, 4 had to be operated upon subsequently, and 4 died. The results of surgical treatment

were much more favorable. The mortality was 12.5% ; but when the cases in which death was due to causes independent of the operation were deducted, the remaining mortality was only 2%. In none of the cases was there a return of stone formation or of colic. Two cases suffered from cramps which were probably connected with disturbances in the celiac ganglia and the abdominal sympathetic. The operation practised was that of **einzeitige cholecystomy** (cholecystostomy at a single operation). Cholecystectomy was performed 5 times, and choledochotomy 7 times. [D.R.]

5.—Grusdew recommends the use of **calcium carbide** in the treatment of neglected and inoperable **cancer of the uterus** for its anesthetic influence, for its remedial effect upon the offensive discharge, and especially for its efficacy in controlling hemorrhage. The calcium carbide may in the form of a powder be blown over the surface of the cancer, or pieces of it may be placed in the crater-like form of the cancer and covered with a tampon. The healthy portion of the vagina should be protected from the burning effect of the calcium by covering it with a tampon, dry or saturated with glycerin. Grusdew considers this method of treatment especially adapted to use in private practice and for ambulatory patients, where other methods are not so available. The erosion and ulceration cease to bleed after the application of the calcium carbide and soon heal, forming a layer of pavement cells. This palliative effect usually continues a week or more, when the application may be repeated. Whether there is any real check to the progress of the disease farther experience can alone determine. [W.K.]

6.—According to Theilhaber, the dangers attending **vaginal irrigation** are: 1. That in sensitive women the shock of a too cold or too hot fluid may cause faintness, shivering, or vomiting. 2. In acute inflammation of the peritoneum the distention of the vagina, especially in case of narrow vaginal ostium and high pressure of the fluid, may increase the peritonitis. 3. In rare cases the entrance of the fluid into an open vein, as has occurred in vaginal carcinoma. 4. The excessive distention of a relaxed uterus from the pressure of the fluid may cause vomiting and severe pain. 5. The passage of the fluid through the tubes into the abdominal cavity sometimes takes place with bad results. To avoid these dangers great care must be exercised, high pressure avoided, and the best instruments used, irrigators being preferred to balloon syringes. [W.K.]

7.—In addition to the customary **symptoms of pregnancy**, Naegeli mentions cases of women who experience symptoms peculiar to themselves, such as itching and burning, swelling of varicose veins, or local peritonitis; and concludes that these are ordinarily a recurrence of some form of disease accompanying former lying-in periods; the "place of least resistance" shows the indication of pregnancy. With some women phlebitis or thrombus of the veins of the lower extremities form a "pregnancy barometer" whose reliability and promptness leaves nothing to be desired. He also describes the peculiar form of the external orifice of the urethra, not as round or oval, but as closed with two-pointed flaps which form an angular orifice. The change in this may also be an indication of pregnancy. [W.K.]

8.—Kiefer reports 2 cases of **gastric ulcer**, the first occurring in a girl of 20, who had been troubled with gastric symptoms for about 5 years. Suddenly, while walking up stairs, she felt a sharp pain in the upper abdominal region; also in the shoulder and arm; and became markedly collapsed. Sixteen hours later, operation was performed and the perforation was found in the stomach near the entrance to the esophagus. A large ulcer was found in this position, and it was necessary to excise it to its whole extent before a secure suturing of the stomach-wall could be accomplished. The patient recovered without deleterious symptoms. Case 2, the patient was a woman of 34, who had suffered with stomach-troubles for 10 years. Diagnosis of *ulcus ventriculi* was made, and operation decided upon. Careful search showed the stomach to be normal and free from any inflammatory thickening. The ring of infiltration, however, was found on the descending part of the duodenum, and in separating the adhesion the ulcer was torn open. As the lumen of the duodenum was very large, the ulcer was excised, and the somewhat oblique defect closed by suture. The suture was reinforced by covering it with a portion of omentum. The patient made a good recovery. [G.B.W.]

June 19, 1900. [47. Jahrg., No. 25.]

1. The Knowledge of the Cause of Primary Iritis, on the Ground of Statistic Collection. MICHEL.
2. Acute Osteomyelitis. E KOCH.
3. Operative Treatment of Inversio Uteri and Observations on its Etiology and Significance. W. THORN.
4. Retroflexion of the Gravid Uterus with Incarceration. KARL REINECKE.
5. Idiopathic Osteopsathyrosis. LUDWIG LANGE.
6. A New Obstetric Hook-Forceps. R. HANSEN.
7. Ascending Traumatic Neuritis Without External Wound. K. BRODMANN.

1.—von Michel has investigated 84 cases of **primary iritis**. He found it more frequent in the female than in the male sex and more commonly unilateral than bilateral. The average age was 40.3 years. Tuberculosis was the cause in 31 cases (33.8%), chronic nephritis in 29 (34.5%), disease of the circulatory apparatus in 13 (15.4%), syphilis in 5 (5.9%), and various other affections in 6 (7.1%). From this study he concludes that general diseases play an important part in the production of primary iritis and that this should always be kept in mind in dealing with such cases. [D.R.]

2.—A case of **acute osteomyelitis** of the sternum in a man of 30, without any definite cause. This particular affection generally attacks the body rather than the manubrium of the sternum and may lead to necrosis of the posterior surface with purulent mediastinitis, to total necrosis of the bone, or to necrosis of the anterior portion without mediastinitis. The involvement of the mediastinum and the adjacent serous membranes makes the disease very grave. There were 5 deaths in 8 cases. The treatment consists in early surgical interference—either trephining of the sternum or removal of the entire diseased bone. [D.R.]

3.—Thorn reports a case of **inversion of the uterus**, which occurred nearly 5 months after labor. The patient was confined in the clinic on September 4, 1899, and at the time of her confinement the middle of the fundus was so hollowed that a bicornate uterus was diagnosed. There was nothing abnormal in the puerperium, however, save some urine-retention. In the latter part of November she suffered from thrombosis of the right and, a few days later, of the left femoral vein. She recovered sufficiently to attend to her household duties, but on the 26th of January a severe hemorrhage came on, and on examination 2 days later, the uterus was found to be totally inverted. The colpeurynter failing to cause reposition, she was brought to the hospital for operation. A bow-shaped incision was made in the anterior wall of the vagina, the bladder pushed away from the cervix, and the anterior wall of the uterus was incised in the manner of Karer. Strong traction was then made on the anterior lip, but without result. As this measure failed, Douglas's pouch was opened and, after breaking up a bridge-like division seemingly adherent to the fundus, the uterus was turned up with difficulty and sutured in place. These sutures were secured with some trouble because of the decaying tissue of the uterine wall. The patient recovered rapidly, leaving her bed on the ninth day, menstruating normally on the twelfth, and leaving the hospital on the fifteenth. Five months later the uterus was absolutely normal in form and position and the patient entirely well. [W.K.]

4.—In the opinion of Reinecke retroflexion of the gravid uterus generally results from a malposition preceding pregnancy. In the majority of cases the pregnant uterus erects itself, since as the anterior uterine wall is distended it draws upward the whole uterine body. Whether any deviation of position will be spontaneously corrected or not seems to depend upon the form of the sacral bones, and of the promontory, also upon the texture of the uterine walls, firmness of texture being unfavorable to reposition and leading to retroversion rather than retroflexion. The second in frequency of the results of this complication is abortion, which is most liable to occur in the fourth month when the small pelvis has become full and it presses upon the further growing uterus, disturbs the circulation in its walls, provokes labor-pains and perhaps causes expulsion of the fetus. When the abortion occurs earlier it usually is due to some mechanical condition, as injury to the ovum or hemorrhage in the decidua, etc. When there occurs spontaneously neither correction of the malposition nor abortion, then as pregnancy advances the woman endures all the troublesome symptoms of the incar-

cerated uterus, pressure in the pelvis, pain in the sacral region, obstruction of the bowels and retention of urine from pressure on the bladder, and the train of distressing and perhaps disastrous consequences. The diagnosis of retroflexion of the gravid uterus is not generally difficult; and the first step in its treatment is the emptying of the bladder followed by reposition of the uterus. If after reposition an examination shows a return of the retroflexion a pessary may be worn until the fifth month of pregnancy. If, however, a reposition is impossible, then the proper treatment is an emptying of the uterus. [W K.]

5.—Lange reports a case of **idiopathic osteopsathyrosis** in a boy of about 6 years. He was perfectly healthy up to the age of 22 months, and then upon very slight cause broke the left femur. Subsequently he had a number of other fractures, altogether 22. They healed very promptly, although with marked deformity in the lower extremities. The tibiae were curved and flattened. The author reviews the literature of the subject. The cause of the disease is unknown. It is possible that it may be connected with disturbances of the trophic nerves. Treatment has been of very little use. In one case thyroïdin seemed to be of value. [D.R.]

6.—Hansen recommends a new instrument for assisting in the delivery of breech-presentations. It consists of an instrument with hooked ends to catch in the curve of the groin and draw down the fetus by rotary traction. [W K.]

June 26, 1900 [47. Jahrg., No. 26]

1. A Case of Apparent Foot-and-Mouth Disease in Man. SCHULTZE.
2. The Working of Digitoxin in its Resemblance to Digitalis Leaves. E. ZELTNER.
3. Agglutinating Capacity of the Blood from a Healthy Child of a Typhoid-Sick Mother. M. ZÄNGERLE.
4. Multiple Neuritis. HENRICI.
5. Reports from the Municipal Diphtheria-Testing Station of Chemnitz. SCHOEDEL.
6. A Case of Infantile Cerebral Paralysis Complicated by Oculomotor Paralysis. K. KISSLING.
7. A Case of Perithelioma of the Carotid Gland. HEINLETH.

1.—A little girl, 2½ years old, had a violent stomatitis, the mucous membrane of the mouth being covered with a dirty exudate. In addition there were pemphigus like eruptions on the fingers and toes and here and there a furuncle. Schultze made a diagnosis of **foot-and-mouth disease**, although no source of infection could be demonstrated, nor was it possible to reproduce the disease by inoculation into animals. The child recovered, but had some scars at the commissures of the mouth as a result of the affection. [D.R.]

2.—A clinical comparative study of Merck's crystallized **digitoxin** and **digitalis leaves**. The author's conclusions are that digitoxin in promptness, energy, and duration of action, is equal and sometimes superior to the mother plant. Its administration by the mouth is less prompt than its subcutaneous or rectal introduction. The dose employed was one tablet of ¼ mgm. (2½ of a grain) 3 times a day. [D.R.]

3.—The blood of an **infant** born of a mother suffering from typhoid fever gave the **Widal reaction**.

4.—Henrici reports a case of **arereñal neuritis**, 3 cases of alcoholic, and one of multiple neuritis of infectious origin—perhaps due to pneumonia. [D.R.]

5.—In a fatal case of **fauical diphtheria** the author found an exudate on the mucous membrane of the stomach in which bacteria could be demonstrated microscopically as well as culturally. Gastric symptoms had been absent during life, but diarrhea had existed. This case led him to examine the mucosa of the stomach and intestines, as well as the feces, for diphtheria-bacilli in cases of diphtheria. In two instances in which the stomach presented nothing abnormal, full virulent bacilli were found on the mucous membrane; also in the intestines, in one of two cases examined. In 8 specimens of feces of diphtheria-patients diphtheria-bacilli were found once by means of Neisser's stain. Ordinarily it is probable that the hydrochloric acid of the stomach is capable of destroying the swallowed bacilli and thus of preventing diphtheria of the stomach. When the acid content is diminished an inflammation of the stomach

is possible. Diphtheric enteritis is very rare, but follicular enteritis is common in diphtheria; and Schoedel believes that this latter is perhaps the result of a specific bacterial or bacteriochemic irritation produced by the presence of diphtheria bacilli in the intestinal contents. Through the activity of the lymphatic elements diphtheric processes of greater intensity are prevented. In the second part of the paper the author gives his experience with Joos' serum agar. This is an alkaline mixture of blood-serum, bouillon, and agar. His conclusions are that for purposes of rapid diagnosis Löffler's serum is the best; for laboratory experiments (the securing of pure cultures, propagation, and biologic studies) Joos' serum-agar is valuable. [D.R.]

6.—A case of **infantile cerebral palsy with complicated oculomotor paralysis** in a girl of 17. The father was tuberculous at the time of the conception of the child. The disease began about the third year with involuntary movements. The eyes presented bilateral nystagmus and paralysis of the right internal rectus; the left eyeball could scarcely be raised or lowered; the pupils were unequal. There was a left sided hemiplegia, including left sided facial palsy. Contractures were not marked. There was no aphasia, nor epilepsy, but intellection was impaired. There were marked athetoid or choreic movements, as the author calls them. He places the lesion in the right cerebral peduncle and assumes, in addition, a slight involvement of the oculomotor fibers on the other side. A discussion of the symptomatology of infantile cerebral palsy accompanies the report. [D.R.]

7.—To the 6 cases of **tumor of the carotid gland** von Heinleth adds another which he observed in a woman of 60 years. The tumor seemed to follow a difficult tooth-extraction with fracture of the alveolar process and a consequent inflammation dating back to 1859. A small tumor developed on the left side of the neck and later two other small tumors appeared above the first, which, however, subsequently again disappeared. On examination in 1896 the author found a moderate-sized goiter and an isolated tumor the size of an apple directly behind the left angle of the jaw. The sternocleidomastoid was stretched over it. The tumor was scarcely movable, hard, and rounded. Slight pulsation was visible. There were no auscultatory signs and the pulsation was due to transmission from the underlying carotid. At operation the tumor was found to lie in the fork of the internal carotid. It was removed by careful dissection with very little hemorrhage; and measured 8 x 5 x 3.6 cm., and had a circumference of 21 cm. The carotids were exposed for a length of 11 cm. after the extirpation of the growth. On section the tumor resembled in appearance a colloid growth. Microscopically it consisted of connective tissue stroma extending in from the capsule, and containing an abundance of vessels and nerves. The trabeculae divided the tumor into lobules, the interior of which was traversed entirely by winding and anastomosing capillaries. Between the capillaries were nests of perithelial cells and on that account the tumor was diagnosed as a perithelioma. The author gives extracts of all of the cases hitherto reported. The tumors seem to begin at the end of puberty and to grow very slowly. They occur with about equal frequency in both sexes. The subjective symptoms are vague. Objectively the symptoms differ from those produced by aberrant goiters, metastatic tumors of lymph-glands, and aneurysms. The position is characteristic—at the bifurcation of the carotid. This produces two symptoms: a certain immobility and pulsation. In only one of the 7 cases, viz., that of the author, was the carotid preserved. In the others either the external or the common carotid and some of the branches had to be sacrificed. Paltauf has pointed out that the passage of a small vessel from the bifurcation of the carotid directly into the tumor is characteristic of origin from the carotid gland. Such a vessel was not present in the author's case, but he still believes that the microscopic features warrant the conclusion that he has drawn. [D.R.]

Centralblatt für Gynäkologie.

June 2, 1900.

1. The Application of Bruns' Airoil Ointment to Laparotomy Wounds. Oskar FRANKL.

2. The Disinfection of the Hands in the Practice of Midwifery. R. KOSSMANN and G. ZANDER.
3. Operative Treatment of Tubal Pregnancy. JUNG.

1.—Frankl describes various forms of stitch-abscesses which sometimes follow **laparotomy** despite all precautionary measures. Even when absolutely sterile metallic sutures are used suppuration occasionally occurs. He holds that the glands of the skin may contain cocci which the most careful disinfection with corrosive sublimate will not render innocuous. Each stitch injures a series of fat glands the serum from which furnishes a medium in which the pyogenic work of the cocci at once begins. By the pressure of the sutures the skin becomes moistened with secondary serum, and also the cocci by this pressure are forced into the deeper tissues and suppuration follows. Bruns claims that the use of his **airol ointment** over the incision makes it impossible that any such infection should occur. Frankl remarks that the bactericidal power of the ointment must be very energetic to reach the deeper tissues and that its eminent antiseptic power can only be proved by experiments and that experiments have value only as the culture material used is similar to that in the human organism. He describes in detail the tests made and reaches the conclusion that although Bruns' ointment has some value, since airol undoubtedly has great antiseptic power; yet, in his opinion, based upon practical experience, airol powder and gauze are to be preferred, as the gauze absorbs the secretions better than the ointment. [W.K.]

2.—Kossmann and Zander report in detail the result of many experiments made to test the relative efficiency of 20% solution of **chinocol** and 3% solution of **carbolic acid** in sterilizing the hands. While admitting that the absolute sterility of human hands is unattainable, their researches show the superior efficiency of the chinocol solution in destroying germs; then it has the additional advantage of not being poisonous and not causing any inflammation of the skin. For these reasons they consider it the best disinfecting agent for common use in obstetric practice. [W.K.]

3.—Jung gives the history of 2 cases of **tubal pregnancy**, successfully operated upon, emphasizing two points, the removal of the product of conception per vaginam, and the preservation of the tube in a condition to perform its normal function. He says that today operative gynecology demands the use of the vaginal way whenever it is practicable; only its impossibility permits the use of laparotomy. The technic is more difficult, it demands more experience and greater patience since it must be performed in the dark; but it is better for the patient and less dangerous, and she is saved from the abdominal cicatrix. Hence the physician must not shrink from the greater difficulties, but learn to overcome them. Yet there are limits to the vaginal operation, such as size of the tumor or greatness of the adhesions, etc. No fixed rules can be given, each case must be governed by the judgment of the operator. In cases involving great injury to the tube, it should be resected; but in rupture with small opening, peel out the ovum or fetus and suture up the slit in the tubal wall. [W.K.]

June 9, 1900.

1. Remarks upon the Article by Frankl in the Preceding Number. WALTER STOECKEL.
2. A Simple, Selfretaining Speculum. STEINSCHNEIDER.

1.—Stoeckel remarks that there has been in the Bonn clinic no cause for dissatisfaction in the use of the **airol ointment** upon laparotomy or other wounds; yet **powder** is preferable to the ointment since it is a much better absorbent of the secretions. He, however, apparently prefers **kaolin**, its great advantages being its nonpoisonous, non-irritating, and odorless qualities, also its great capacity for absorbing moisture, its fineness of grain and great volume of pores. The kaolin should be sterilized by being placed 24 hours in a temperature of 130° C. The dryness of the suture is the first basic condition of primary healing and this is best obtained by the use of kaolin. This elimination of all moisture is also a great preventive of secondary infection. Kaolin powder though can not be used to the best advantage in perineal or other incisions where it cannot be kept in place with bandages. Stoeckel, however, makes the remark that in his clinic the best healing of incisions was obtained with purely antiseptic bandages. [W.K.]

2.—Steinschneider describes the construction of a speculum which he designates as the "**Regenschirm**" or **umbrella speculum**. It is made of wire 2 mm. in thickness and 16 cm. in length, bent in 4 loops and when complete is about 25 mm. in diameter. Its advantages are that it is easily introduced into the vagina, is selfretained, and makes visible not only the vaginal portio, but also the vaginal walls. It is light, simple in structure, and easily sterilized. [W.K.]

June 16, 1900.

1. Cervical Distention and Rupture. HAMMERSCHLAG.
2. The Treatment of Eclampsia. POPESCU.

1.—Hammerschlag reports a case of **distention and rupture of the cervix** occurring in an octipara, aged 37, whose previous deliveries had all been spontaneous and rapid. The assistant physician had diagnosed the case as one of breech presentation; but when the hospital physician arrived the child was found to be in the abdominal cavity with its head in the pelvic passage. Cranial perforation was performed on the already dead child, and the mother removed to the hospital to be delivered by laparotomy. She died, however, a few minutes after her arrival, but a subsequent section showed that the cervix had been distended to a very great length, about 16 cm., and then ruptured. The author has found in all the literature accessible to him no similar case of rupture of the cervix. [W.K.]

2.—After quoting statistics from Zweifel, Olshausen, and others, showing that there is a considerable percentage (from 15% to 35%) of cases of **eclampsia** in which the convulsive attacks do not cease after the emptying of the uterus, Popescu discusses the medical procedure adopted to complete a cure. He refers to varying opinions as to the use of chloroform, morphin, and chloral with their uncertain and sometimes dangerous consequences, and then relates his own experience with a comparatively new preparation which he calls "**bromidia**," and a tablespoonful of which contains about 3 gm. of pure chloral and kali bromati and 2½ cc. extract hyoscyam. and extr. cannab. ind. A tablespoonful is to be applied as a clysm by a balloon syringe; or a smaller dose, a teaspoonful, might be used when morphin had been previously administered. Popescu reports 2 cases in which he used bromidia with excellent results. The first was a primipara in whom the eclamptic attacks, beginning before delivery, continued after with increasing frequency and violence until it became necessary to fasten her on the bed with bandages. Repeated doses of morphin and chloroform had been given and he had given up the case as lost, when, remembering having once used bromidia, he now applied 20 cc. as a clysm with a balloon syringe No. 2. The patient had no subsequent attack, but lay in a heavy sleep or stupor for 2 days, only arousing sufficiently to urinate spontaneously or take a swallow of water. On the third day consciousness returned and she began to take nourishment. In the second case the attack was less severe, the dose was smaller, and the patient's consciousness returned the next morning. Eclampsia is a disease of such gravity, and the influence of bromidia upon it is so obvious, the author thinks the preparation is worthy of consideration as a welcome contribution to its medical treatment. [W.K.]

Ovarian Pregnancy.—Catharine van Tussembroek (*St. Louis Courier of Medicine* July, 1900), presents a careful analysis of a specimen in a case of ruptured ovarian pregnancy, bearing upon this much disputed question. She details a number of changes in the physiologic growth and development of the ovum and proves that pregnancy may occur in a graafian follicle as a result of the rupture of a follicle without the discharge of the ovum. The opening of the follicle permits the entrance of the spermatozoa to the ovum and following such fertilization the opening closes or remains patent. She failed to find with the most careful search, any formation in the wall of the follicle resembling decidua tissue, and concludes from this that this tissue is not essential to the implantation and growth of ovum. She claims also that the syncytium is entirely of fetal origin and not a product of the maternal epithelial tissue. She favors the conclusion that many so-called tuboovarian pregnancies are of ovarian origin. [M.B.T.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Lumbago.—According to Nestor Tirard (*Medical Treatment of Diseases and Symptoms*) the following mixture is often useful in some forms of lumbago:

R.—Sodium salicylate..... 10 grains.
Potassium iodid 5 grains.
Fluid extract of sarsaparilla..... 2 drams.
Water to make $\frac{1}{2}$ ounce.

To be taken in water thrice daily, after meals.

Sanatorium Treatment of Phthisis.—Muthu (*Treatment*, June, 1900) director of Inglewood Sanatorium, Isle of Wight, writes that many patients put on weight almost the first week. The average gain is from 6 to 8 pounds in 4 weeks. The best results are obtained if patients are treated in the early stage and the treatment is continued for at least 6 months. This new treatment does not suit all patients. Patients in the advanced stages have no chance of complete recovery. Consumptives with bronchial catarrh and incessant cough do not get on very well in the open air. Patients with a temperature below 100° F. do not run any risk in being exposed to fresh air. But if the temperature is above 100° F. or the evening temperature high and persistent, the open-air treatment should be modified.

Above all, the secret of success of the open-air treatment depends upon the strong personality of the medical attendant. Indeed, the man at the helm is such an important factor as to become quite indispensable to the treatment. The success depends upon the ability of the doctor to discriminate and to shape his treatment according to the physical and mental wants of each individual case; the patient must not be made to feel that he is merely an inmate of an institution the régime and regulations of which he has rigidly to observe, but, rather, that he is a well-liked guest, who, while conforming to certain rules of the house for the benefit of his health, is at liberty otherwise to enjoy life in his own fashion.

Vomiting of Pregnancy.—Neall (*Lancet*, February 3, 1900) has found the following combination useful:

R.—Potassium bromid 2 drams.
Solution of strychnin..... $\frac{1}{2}$ dram.
Chloroform water to make 3 ounces.
One-twelfth part to be taken in water 3 or 4 time a day.

Hypnotic Action of Apomorphin Without Nausea.—Douglas (*Merck's Archives*, June, 1900) states that apomorphin acts as a prompt and well-nigh infallible hypnotic, if injected subcutaneously in doses of about $\frac{1}{30}$ of a grain. Although this is about the average dose, yet for some patients this is too large, as it produces nausea, while in others a larger amount will cause no disagreeable symptoms. The dose should be so adjusted as to be large enough to produce sleep and small enough to avoid nausea. The sleep from this remedy is refreshing and restful. As its action is prompt, it is advisable to administer it when the patient is in bed or quite ready for bed. If a delirious patient refuses to go to bed, this hypnotic will cause him to voluntarily lie down in a few minutes, and sleep will follow. Its direct hypnotic action appears to last from 1 to 2 hours, but in many cases the patient will sleep all night, if promptly put to sleep by this remedy on going to bed. During the last 4 years Douglas has given apomorphin in private and sanatorium practice to 300 patients, during that time he has found but 2 or 3 individuals on whom it had but a slight hypnotic effect. The advantages of apomorphin as a hypnotic are: safety; promptness—producing sleep in less than half an hour, and frequently in 10 minutes; certainty of action in most cases, even in the wildest delirium; refreshing and natural character of sleep, and no danger of habit.

Rectal Injections of Codliver Oil in Tuberculosis.—Zauner (*Therapeutische Monatshefte*, June, 1900) has obtained good results from the rectal injection of digested codliver oil. The injections did not exceed 4 ounces and

were given once daily, an hour after a natural movement or after the bowel had been cleansed by a simple enema. The fluid was warmed and injected slowly, the patient being in the knee-elbow posture. The emulsion of oil should be alkaline or at least not acid. The following formula is recommended:

R.—Pancreatin..... 2 parts.
Insapissated ox-gall..... $\frac{1}{2}$ part.
Sodium chlorid $\frac{1}{2}$ part.
Water..... 20 parts.
Codliver oil..... 100 parts.
Digest for 2 hours.

Repeated Lumbar Punctures and Hot Baths in the Treatment of Cerebrospinal Fever.—The Paris correspondent of the *Therapeutic Gazette*, July, 1900, writes that Netter at a recent meeting of the Medical Society of the Hospitals called attention to the value of hot baths and repeated lumbar punctures in the treatment of suppurative cerebrospinal meningitis. Netter had observed 7 cases since May, 1899, and on the spinal column being tapped in the lumbar region, there was drawn off a yellowish liquid, which on being allowed to stand gave a yellowish deposit of pus containing the *Diplococcus meningitidis* of Weichselbaum. Sometimes a second puncture was made, and sometimes 8 to 10. The purulence and virulence seemed to diminish each time. A complete recovery was obtained in 5 cases; a sixth case presented subsequent ankylosis of two articulations which had been already affected during the disease. As for the seventh case, the symptoms observed showed that the ear, and more especially the labyrinth, was affected, and it was impossible as yet to be sure of the ultimate result. Excellent results were obtained from the use of hot baths. These were given at a temperature of 100° to 104° F. for a period of 20 minutes to half an hour, and administered night and day every 3 or 4 hours. This treatment should be applied as well to the serous as to the suppurative forms. The patient should, in case of need, be given injections of serum.

Acute Rheumatism.—Sansom (*Lancet*, April 21, 1900) recommends the following combination:

R.—Sodium salicylate..... 20 grains.
Aromatic spirit of ammonia..... 20 minims.
Camphor water..... 1 ounce.

To be taken every 2 hours until 6 doses have been taken or until temperature has fallen, and pain has ceased, subsequently to be taken every 6 or 8 hours. He finds that sodium salicylate is not incompatible with free ammonia or aromatic spirit of ammonia, and that the above mixture shows no decomposition and is readily taken by patients.

Creolin in Eczema.—Walsh (*The Therapist*, March 15, 1900) states that in eczema and other acute inflammatory conditions, creolin may be used as an extremely weak lotion, half a dram to the pint of warm water, sponged over the parts two or three times daily, and followed by a dusting powder of zinc oxid or calamin, 2 drams to the ounce of starch. To this it will be well to add a mild antiseptic, as salicylic acid (10 grains to the ounce), or eucrophen (30 grains to 1 ounce). As the inflammatory condition subsides, an ointment of creolin may be applied in a strength gradually increased from 10 to 30 minims to an ounce of vaselin. The chief point to remember in using creolin for acute conditions is to apply it well diluted and to combine it with soothing remedies, such as calamin. When the eczema becomes chronic or the disease is a scaly one, such as psoriasis, then creolin becomes a valuable remedy. Unna calls the tar compounds "reducing" agents, because they absorb oxygen and lead to the formation of healthy epithelium. Creolin may be rubbed into dry patches of the kind mentioned in a strength of $\frac{1}{2}$ to 1 dram to the ounce of vaselin. It may be advantageously combined with salicylic acid, especially when there is much scaling. In both sub-acute and chronic conditions it is well to add a mild mercurial preparation, as in the following formula:—

R.—Creolin.....30 grains.
Ammoniated mercury10 grains.
Vaselin 1 ounce.
Make into an ointment.

MILITARY SURGERY.

By W. C. BORDEN ("EDRO"), M.D.*

Captain Medical Department U. S. Army; Professor of Surgical Pathology and Military Surgery, Georgetown University, Washington, D. C.

(Continued from page 252.)

At mid range lateral impingement of the bullet generally produces oblique fractures with little comminution, as shown in Figure 9.

Even at long range the small-caliber bullet usually produces complete fracture of the shaft with some comminution; though this is not always the case, as British surgeons in South Africa report some cases in which the Mauser has even made clean-cut perforations of this part of the bone.

EFFECT OF THE SMALL-CALIBER BULLET ON THE EPIPHYSES OF BONES AND ON SPONGY BONES GENERALLY.

In the extremities of long bones, the effect is quite different from that in the shaft. The lateral energy is not so well transmitted, and even at short range extensive comminution is rare. The almost clean perforation made by a Krag-Jorgensen bullet at extremely short range is shown in Figure 10.

FIG. 9.—Radiograph showing oblique fracture of humerus from lateral impact of bullet; mid range.

* The paper signed "Edro" was awarded the Sinder prize (a gold medal) for the best paper on military surgery, submitted for competition at the annual meeting of the Association of Military Surgeons of the United States, held in New York City, May 31 to June 2, 1900. The committee of award consisted of Brig.-Gen. J. D. Griffith, Surg.-Gen. N. G. Mo.; Medical Director Geo. W. Woods, U. S. Navy; and Major A. C. Girard, Surgeon U. S. Army, and all papers were submitted to the committee with their *nommes de plume* only.

As the shattering effect of the small-caliber bullet upon the articular ends of long bones is usually not great even at short range; at median and long range, clean perforation, guttering, or fracture without comminution is the rule in those parts of the bone.

FIG. 10.—Radiograph showing perforation of upper end of tibia by a Krag-Jorgensen bullet; range 10 feet. Girard¹⁸ reports a like effect in the lower end of the tibia at short range, and several cases of perforation of the epiphyses occurring in the Spanish American War have come under my observation.

The spongy bones of the tarsus and metatarsus and other parts are seldom badly shattered at any range, and perforation without fragmentation is the rule. The bones of the face are almost as invariably perforated as cleanly as are the soft tissue, La Garde¹⁹ having made special note of this as a result of his experience in the Spanish-American War.

Before discussing the wounds of regions, the effect of deformed and deforming small-caliber bullets and lodged missiles and wounds by shell, shrapnel, revolver, saber, and bayonet have to be considered.

WOUNDS BY DEFORMED AND DEFORMING BULLETS.—As before noted, the compound bullet frequently ricochets with great force and though very resistant to deforming violence is often deformed by ricochet impact. (Figs. 1; Nos. 3, 4, 5, and 6.) When deformed it no longer produces typical wounds, but may produce extensive laceration both of the skin and subcutaneous tissues. (Fig. 11).

Wounds so made have undoubtedly often been attributed to the intentional use of deforming missiles of the dumdum type. These deformed bullets often make wounds so large that they may be thought to have been made by fragments of shell, and even when traveling with low velocity may shatter the shaft of a bone as badly as would the same bullet at short range when undeformed. (Fig. 12.)

Aside from the extensive traumatisms produced by deformed bullets, the gravity of the wounds made by them is greatly increased from the fact that the bullets are usually infected from striking the ground or surrounding objects at ricochet impact; and from their irregular shape are very apt to carry dirt or pieces of

FIG. 11.—Wound by ricochet Mauser. Photograph by Acting Assistant Surgeon Edward J. Meyer, U. S. Pot. A. G. R., 7th U. S. Inf., was bending over rock on which bullet struck and ricocheted making large lacerated wound and fracturing seventh rib. Internal and external hemorrhage from lung. Air escaped through wound. Patient fainted, on recovery stuffed first-aid dressing and handkerchief into wound. Recovery complete at the end of two months.

clothing into the wound, while the latter is usually so large and ragged that it is easily infected. Similar properties are possessed and similar effects are produced by deforming bullets of the dum dum type.

It follows that the treatment of wounds made by deformed or deforming bullets cannot be along the same lines as that adopted in wounds made by undeformed bullets. The ragged nature and infection of the wounds will frequently necessitate active operative treatment—the removal of bone-fragments and contused and lacerated tissues and treatment by open antiseptic methods. Also amputation of extremities may occasionally be demanded on account of the excessive traumatisms produced, especially if accompanied by infection.

WOUNDS BY SHRAPNEL.—The shrapnel bullet now used is a soft lead bullet measuring 1.25 cm. in diameter and weighing a little over 11 grams (Figures 1: 8). The velocity of these bullets is low, being only that of the bursting charge of the shrapnel, and the bullet, therefore, belongs to the large-caliber, low-velocity type. Theoretically wounds produced by these missiles in the soft tissues should differ materially in their character, course of healing, and aseptic quality from those produced by the small-caliber bullet. Practically this is by no means always the case, as in the experience of the writer, of the seven shrapnel wounds seen by him in the Spanish-American war, but three suppurated and in these cases suppuration was the result of the removal of the bullet in the field. In the other 4 cases the wounds of entrance were so like those made by the small-caliber bullet and irritative symptoms were so lacking that, until the Röntgen-ray was used, the wounds were thought to have been made by small-caliber bullets. This is a strong argument for modern methods. Had these large lead bullets been probed for under septic conditions in the field, instead of being left undisturbed

under the impression that they were Mauser bullets, a very different result would probably have been chronicled.

From their low velocity, shrapnel bullets are usually deflected from their course by bones and rarely fracture them. This, however, does not always occur, as a case of clean perforation of the lower end of the femur without fracture, which came under the writer's observation, proved to have been done by one of these missiles—but such cases are undoubtedly rare. Neither is the destructive effect of these missiles upon organs always as great as might be expected from their size, as Treves¹⁶ reports the case of an officer in whom, although a shrapnel bullet passed through both liver and kidney, beyond a little collapse, some temporary tympanites and hematuria, no trouble of any kind appeared.

It therefore appears that wounds made by this missile should be treated along the same lines of those made by the compound bullet.

REVOLVER BULLET WOUNDS.—A small-caliber revolver has recently been adopted in most armies. With this weapon, wounds similar to those made by the small-caliber rifle may be expected, but from the shorter range of the arm and from its being carried only by cavalry, wounds from it will be comparatively few in number. Wounds by the old, large-caliber revolver will be still less frequent and will usually only occur as a result of accident, or homicidal or suicidal intent. The wounds made by this weapon closely resemble those made by the shrapnel ball.

LODGED MISSILES.

RIFLE BULLETS.—The penetrating power of a missile, depends upon its velocity, weight, sectional density and form. All these factors are such in the missile projected by the modern rifle as to give it great penetrating power. This is so great, compared to that of the old

FIG. 12.—Radiograph showing comminuted fracture of femur by lodged, deformed, Mauser bullet. The wound was infected, 11 fragments of bone were removed and recovery with a shortened but useful limb resulted.

lead bullet, that while the Springfield lead bullet, caliber 0.45, at three feet from the muzzle will penetrate about three inches of oak, and that with marked deformation,

the new bullet will penetrate about 19 inches of the same wood and remain undeformed (Figure 13).

From its great penetrating power, experimenters argued that lodged missiles would be very infrequent in wars where the small-caliber rifle is used. There are, however, two main factors which determine lodgments

FIG. 13.—Relative perforating power of the small-caliber rifle bullet in hard oak at three feet from the muzzle.—(La Garde.)

of the ball: (a) low velocity either from long range or ricochet impact, and (b) deformation of the bullet.

The frequency of lodged Mauser bullets in the Santiago campaign has been commented upon by all surgeons who saw the wounded. In 198 Mauser wounds seen by me, there were 21 lodged bullets. On the other hand, in the Anglo-Boer War, reports up to the present (April 1, 1900) show an extreme rarity of lodged balls in the British wounded, though the Boers are using the same arm as did the Spaniards. It was thought that the ammunition used by the Spaniards in Cuba was defective; but La Garde, in testing it to determine this point, found no defective shells. Lodgment of the missiles, therefore, must rest mainly upon the conditions under which the engagements are carried on. In my cases, with few exceptions, all lodged missiles which were removed, were found deformed, indicating that their velocity had been lowered by coming in contact with some obstacle before entering the body (ricochet). In several cases the deformity was so great as to cause surprise that the bullet could have retained sufficient velocity to produce a penetrating wound, and especially to shatter a bone as it did in some instances (Figure 12.)

In a number of cases I have seen the lodged bullets were found butt end foremost, showing that the missiles had impinged against some obstacle and turned end for end before entering the part (Figure 14).

It would appear therefore, that conditions of terrain and the manner in which the fighting is carried on will largely influence the percentage of lodged bullets. In wooded districts and at long range conditions under which much of the fighting was done at Santiago—many lodged missiles may be expected from low velocity due to long range or to impingement of the bullets against trees. Also, when men are in intrenchments or lying prone, bullets may strike the ground or trench before inflicting a wound. On the other hand, in an attacking force in the open—a condition which appears to largely obtain with the British in the Boer War—the percentage of lodged missiles will be small.

With shrapnel, lodgment of the bullet is very common and fragments of shell and secondary missiles are also frequently lodged.

TREATMENT OF LODGED BULLETS.—It is well known that lodged missiles often become encysted in the tissues and cause no trouble. In other cases they produce trouble by inducing suppuration or cause pain or neuritis by pressure upon a nerve, or interfere with motion by implicating a joint. Also, knowledge of their presence sometimes gives rise to mental disquiet-

tude even though the bullet is doing no harm. In consequence, the questions for the military surgeon to determine are: (a) whether or not to operate for the removal of the foreign body, and (b) when the operation should be done. In reply to the first question, the answer is, *that a lodged missile should always be removed when it is producing distressing or dangerous symptoms, if its removal is possible and does not endanger life or necessitate operative traumatism which will produce effects more serious than will arise from allowing the missile to remain in situ.* It would be manifestly improper to allow a missile which is doing harm to remain in the tissues, provided it could be removed with safety to the patient: and equally, it would be unsurgical to remove, or attempt to remove, a missile when the operation would be more immediately dangerous or entail greater future dangers or discomforts to the patient than would the presence of the foreign body. In reply to the second question: as to *when* a lodged missile should be removed, the answer is that *a lodged missile should never be removed in the field or in the field hospital unless aseptic technic is available or the danger arising from its presence is greater than that likely to result from the infection which will occur as a result of operating under septic conditions.*

If lodged missiles are removed on the field or at the field hospital, infection nearly always occurs from the almost absolute impossibility of doing aseptic work under the conditions which obtain at the front. If infection occurs, recovery of the patient is delayed and even if no other serious results supervene, the functions of the wounded part are apt to be impaired in consequence of the cicatricial formations which result. Probably no single measure has done so much to in-

FIG. 14.—Radiograph of Mauser bullet imbedded butt-end foremost in the lower end of the tibia. There was no splintering of the bone, and the bullet was so firmly fixed that much force had to be used to dislodge it.

crease the gravity of gunshot wounds as the search for and removal of bullets, as was formerly the routine practice in military surgery.

The *probing of bullet wounds* should be entirely abandoned except in cases of urgent necessity. Recent experience has shown that most bullet wounds, even those made by large lead bullets, will generally heal without inflammation or suppuration if left alone. When it is necessary to search for a bullet, the operation should be conducted under conditions of rigid asepsis. But even then, it must be remembered that inflammation may be set up. La Garde and others have shown that while bullets in original packages are usually sterile, this is not the case after they have been handled and carried in the cartridge belt, and that firing infected bullets does not sterilize them. Also Habart, Delorne, and Taulhauber have shown that wounds made by the small-caliber bullet are seldom found free from minute particles of woolen, cotton, or linen fiber carried in from the clothing. All bullet wounds, therefore, may be considered as infected, but not to an extent sufficient to cause inflammation—the natural resistance of the tissues being usually sufficient to overcome the infection present in these cases. If, however, tissue resistance is lowered or recuperative work is interfered with by additional traumatism either by probes, instruments, or the finger, though these be sterile, inflammation may be set up in wounds which would otherwise go on to uninterrupted healing. For this reason it is usually better to remove a lodged missile through a new opening made directly over it, unless it lies directly in the entrance wound. It is here that the great benefits arise from the use of the Röntgen-ray, in that it makes possible the localization and removal of lodged missiles without interfering with the original wound.

When a probe has to be used, it should be remembered that, unlike the lead bullet, the steel jacket of the new bullet leaves no stain on the porcelain tip of a Nelaton's probe and that it is, therefore, frequently difficult with a probe to distinguish the bullet from the fragments of bone among which it may be lying. This has been remarked upon by Treves,¹⁰ who points out the advantage of the *telephonic probe* and states that he has used it to advantage in such cases with the wounded of the Anglo-Boer War.

The Röntgen-ray in the Localization of Lodged Missiles.—Immediately upon the discovery of Röntgen radiation, its application to the localization of lodged missiles was recognized and it was used by the British in the Terah and Soudan expeditions. Surgeon-General Sternberg supplied several of the larger military posts in the United States with apparatus, and, upon the outbreak of the Spanish-American War, the principal general hospitals and the hospital ships were furnished with these appliances. Their use has proved so valuable that the British are now using several in the Anglo-Boer war. The use of these apparatus has demonstrated that they are an indispensable diagnostic resource to the military surgeon. (Senn.) By their use, lodged missiles may be located without subjecting the patient to inconvenience, or to danger of infection from probing the wound. In fact, the Röntgen-ray has largely supplanted the probe and should entirely do so except in those rare instances where immediate localization of the bullet is demanded and the Röntgen-ray is not available.

The apparatus for the production of the Röntgen-ray are of two main types, the coil and the static. Both types have been used with success, but are totally unlike in construction.

A *coil machine* was used by the British in the Terah

and Soudan campaigns, and several were in use in the United States army during the war with Spain. In this apparatus, the primary electrical current is supplied either from primary batteries, accumulators, a dynamo, or from a local electrical installation. With the coil apparatus, either a primary battery must be used or the current from a dynamo must be available. The latter is rarely to be had at military hospitals other than those near large cities, but is always available on hospital ships. When a dynamo current can be had, a good coil machine is probably to be preferred to any other kind. In the absence of this source of electrical supply, apparatus operated by batteries gives excellent results. Battery apparatus have the advantage of being fairly portable and of being capable of installation at any hospital. The best type is that operated by the Edison-Lalande cells, as this battery gives the steadiest output of any primary battery now made.

In the *static machine*, the necessary current is produced directly by the revolution of large circular glass plates. This apparatus has the advantage of requiring no electrical plant or battery. It can be operated by hand, but the work is very tiring and motor power should be used. It gives excellent results, but from its size and weight it is adapted only to permanent hospitals.

The experience of the writer with different types of machines, leads him to the conclusion that the coil type operated by a dynamo is best for hospital-ships and for hospitals where a dynamo current is available, and that for base and general hospitals with no such current, a coil machine operated by Edison Lalande cells will give the best results with least trouble and expense.

But even the most portable of these apparatus are bulky, heavy, somewhat difficult to transport, and their use requires considerable experience, and at field hospitals necessitates expenditure of time when surgeons are most busy with work incident to active operations. These disadvantages should not be considered were the benefits to be derived from the employment of these apparatus in field hospitals at all in proportion to the difficulties incident to their transportation and use. This, however, is not the case, for the benefits derived from using them at advance hospitals are confined to few, if any, cases, and the time, work, and transportation required for them can be better employed in other ways. This leads to the formation of the opinion that *Röntgen-ray apparatus should not be used at the front or at field hospitals.* This conclusion, in addition to the above reasons, is based upon the following: (a) Lodged missiles only in *extremely* rare cases require immediate removal; (b) that Röntgen-ray apparatus in the field are an additional incentive to surgeons to operate under conditions not adequately aseptic.

The necessity for noninterference with gunshot wounds at the front or in the field hospital has already been considered. This sentiment has been emphasized by no less an authority than von Bergmann; and Kuttner, as a result of his experience in the Greek War, states that their application in the field is very limited and that while they are of great importance for surgical aid in war, they should be installed in fixed hospitals only. In fixed hospitals and on hospital ships they can be properly operated and managed, and cases requiring their use can be transported to these hospitals and Röntgen-ray observation can there be followed, when necessary, by proper aseptic or antiseptic operative treatment.

This plan of locating and using Röntgen-ray apparatus

was exclusively followed in the Spanish-American War and with the best possible results.

Shell Wounds.—Treves, speaking of the British wounded of Spion Kop, says the shell wounds were the most terrible and the most difficult to treat.¹⁰

Shell wounds differ entirely in character from bullet wounds, and the mistake must not be made of supposing that they can be treated in the same manner. They are made by irregular fragments of metal, are lacerated and unlike bullet wounds are always infected, and if a bone is fractured the comminution is often very great. (Figure 15)

The infection present in these wounds necessitates that they be treated on lines of antiseptics rather than asepsis and consequently the same conservatism cannot be practised as with aseptic bullet wounds. Shell wounds in many ways resemble railroad traumatism and have to be treated on the lines of general surgical

FIG. 15.—Showing extensive comminution of lower end of humerus and upper part of ulna. A fragment of shell carried away all the soft parts at the back of the elbow and amputation was necessary.

principles. The amount of injury to the soft parts and bone have to be considered in connection with the infection, and active interference rather than conservatism has to be practised. The thorough employment of antiseptics, with removal of all bone fragments and careful treatment of the lacerated soft parts, will usually be necessary. Amputation will often be required in these cases, much more frequently, certainly, than in bullet traumatism.

The risks of conservatism in shell wounds involving bones are always great; for as these wounds are always infected the surgeon will have to decide in each case whether the benefits which may be obtained by conservative treatment overbalance the danger to the patient from osteomyelitis, septicemia, prolonged suppuration, and, in bad cases, recovery with a limb at best function-

ally defective from deep cicatricial formation. It is in this class of wounds that antiseptic methods and operative interferences will come most into play as savers of life or limb.

Saber, Bayonet, and Lance Wounds.—Wounds by these weapons furnish the smallest number of traumatism received in war. In the Civil War, among the Federal troops but $\frac{3.7}{100}$ of 1% of all wounds were due to these weapons. In the Franco-Prussian War, among the German troops $1\frac{3}{10}\%$, and in the Russian-Turkish War, $\frac{9.9}{100}$ of 1% were wounded by these weapons.²⁰

Unlike the wounds produced by bullets, these traumatism present no peculiarities which differ from traumatism frequently received in civil life. Their main characteristics resemble those of wounds inflicted by shells and may be considered in the same class, in that they are generally more or less lacerated, or involve a considerable extent of skin surface and are usually if not invariably infected. For this reason they are to be treated on general surgical principles, and especially by recourse to antiseptic methods.

WOUNDS OF REGIONS.

Aside from the character of wounds, the region of the body in which a wound occurs is an important element in considering its gravity and the prognosis of the case. This is due to the structural peculiarities of different parts of the body and to the presence in certain regions of important or vital structures or organs, injury to which may render a wound of grave importance. For this reason, consideration of the frequency with which different regions of the body are subjected to the traumatism of war and the comparative mortality of the wounds in each region, is of importance to the military surgeon. In Table 5, statistics relative to these points are given for two wars—the American Civil and the Spanish-American War. Statistics from the Anglo-Boer War will be of great interest as giving more complete conclusions, relative to the effect of modern weapons, than can be arrived at from the statistics of the Spanish-American War, where the wounded were much fewer in number.

WOUNDS OF THE HEAD.

Flesh wounds of the head may be considered of minor importance, as they rarely lead to fatal results. Of the 40 flesh wounds of the head reported in the Spanish-American War, none were fatal; and even in the Civil War, before the adoption of antiseptic methods, but 162 cases were fatal out of 3,496 flesh wounds of this part of the body.

Wounds of the skull or its contents cause a large percentage of deaths upon the battlefield; for in 64 killed in the Santiago campaign, where cause of death was reported, 26 were killed by gunshot of the head. These wounds also cause high mortality of the wounded (Table V). These immediately or remotely fatal results arise mainly from injury to the intracranial structures. The cranial contents are injured: (a) By direct effect of the missile; (b) by secondary injury from injury of the skull. Direct injury to the structures within the skull is due to direct destructive effect of the missile upon the structures through which it passes; and, in the case of bullets at high velocity, to this effect combined with lateral transmission of its energy (explosive effect). Thus the missile may cause death by striking some vital part of the brain or by severing a bloodvessel. The small-caliber bullet, when at high velocity, un-

doubtedly produces an explosive effect on the skull and brain. This is due to two factors: (a) explosive effect on the skull bones due to the fact that their compact structure readily transmits the energy of the bullet; and (b) from the same effect on the brain, which being a fluid-saturated organ also readily transmits the energy of the bullet, as was pointed out in the discussion of explosive effects. In consequence, there results, at short ranges, a more or less complete disruption of the brain and extensive fragmentation of the skull. The transmission of bullet-energy by the cranial bones is of great importance, for it frequently causes extensive fractures of the inner table of the skull, where the bullet

well, and that such operations have been numerous.¹⁰ In perforating wounds of the skull, the more obliquely the bullet enters, the greater will be the damage to the inner table, and even when the entrance and exit wounds are at right angles to the plane of the skull, the inner table is always more or less broken up at the aperture of entrance (Dent).

In a certain number of cases, however, the small-caliber bullet penetrates or perforates the skull and the brain with little traumatic disturbance and with astonishing immunity to the person wounded. Numerous instances of perforation of the brain have been noted by observers during the Anglo-Boer War and the Spanish-

TABLE V.—NUMBER, REGIONAL DISTRIBUTION AND MORTALITY OF GUNSHOT WOUNDS IN THE WOUNDED WHO CAME UNDER TREATMENT IN THE AMERICAN CIVIL WAR AND SPANISH-AMERICAN WAR.

has "guttered" or grazed the outer table only. Particular attention is called to this by Dent,¹¹ who remarks upon the number of British wounded in the Boer War, in whom the outer table was simply grazed or "guttered" and yet the inner table was extensively fractured or splintered. He strongly recommends that every case where the skull is "guttered" or even slightly grazed be trephined, for the reason that injury to the brain is almost sure to have occurred, and states that when this is done the extent of underlying damage has usually excited astonishment. Further, he states that this course of treatment has been followed by excellent results. Treves, in speaking of his experience in the same war, states that, generally speaking, operations upon the skull for gunshot wounds have done exceptionally

American War. These perforations were not confined to any particular line, but on the contrary were in almost every direction, and yet recovery followed in many instances. Traumatism of this character are undoubtedly produced by the small-caliber bullet only when at low velocity. They correspond to the perforations made in compact bone, or fluid-saturated organs by that bullet under similar conditions. The tolerance of the brain to the injuries inflicted in this way and even to lodged bullets is sometimes remarkable. This is instanced in a case reported by Girard and published by Forwood.¹ (Fig. 16.)

These wounds of the brain and similar ones of the abdomen have produced the greatest surprise and have been the most commented upon by military surgeons.

They really, however, furnish only a small minority of cases and their remarkable character, rather than their frequency or importance as factors in accounting for a lowered mortality of the wounded, is the reason for the great interest they have excited,

It has been shown by Table II, that the mortality of the wounded has been greatly decreased in recent wars.

Large-caliber rifle used:

Civil War.

Federal troops, of the wounded, 6.7 recoveries to 1 death.

Franco-Prussian War.

German troops, of the wounded, 8 recoveries to 1 death.

Small-caliber rifle used:

Spanish-American War.

American troops, of the wounded, 14.1 recoveries to 1 death.

Anglo-Boer War.

British troops, of the wounded, 19 recoveries to 1 death.

(Up to January 27, 1900.)

The question arises as to whether the decreased mortality of the wounded in war since the adoption of the small-caliber rifle is in any part due to a decreased mortality among those of the wounded who have sustained injuries involving the skull or brain. Statistics

FIG. 16.—Photograph and radiograph of Private J. G., 1st Neb. Vol. Mauer bullet entered above left eye and lodged in brain to left of median line. Recovery with no paralysis. Photograph taken 15 months after receipt of injury.

on this point from the Anglo-Boer War are not available, but the statistics of the *Spanish-American War* show practically as high a mortality of the wounded who received skull or brain injuries as has occurred since the *Crimean War*. (Table VI.)

TABLE VI.—NUMBER OF CASES OF WOUNDS OF THE HEAD INVOLVING THE SKULL OR ITS CONTENTS, AND THE MORTALITY IN THIS CLASS OF WOUNDS.

	NUMBER.	DIED.	PER- CENTAGE OF DEATHS.
Crimean War—English	230	170	73.9
Crimean War—French	440	546	73.8
Italian War—French	258	119	46.1
Civil War—Union forces	4,022	2,459	61.2
Franco-Prussian War—Prussian troops .	1,527	783	51.3
Spanish-American War—American troops.	31	18	58.4
Average mortality	60.7

From this it may be stated that notwithstanding the advantages of modern surgery the greater destructive effect of the small-caliber rifle has maintained the gravity and fatality of wounds of the skull and brain. It

may be that full statistics of the Anglo-Boer War will modify this statement to some extent, but the statistics show that the occasional occurrences of recovery after gunshot wound of the skull or brain should not blind the military surgeon to the extreme gravity of these cases.

THE SCOPE AND AIM OF THE WORK OF THE SECTION OF TROPICAL DISEASES.¹

By COLONEL KENNETH MACLEOD, M.D. (RET. I.M.S.)

President of the Section.

THE war in South Africa has stimulated into vivid reality the unity and solidarity of the British Empire. The imperial idea implies not only a community of interest—social, commercial, and political—between the mother country and her colonies and dependencies, but also a community of suffering; and as tropical conditions and tropical diseases prevail in Great Britain to such a large extent, the study of these as they affect both the governing and the governed has come to be recognized as a matter of vital and cardinal necessity.

A knowledge of the pathology and pathogenesis of disease must obviously precede and guide preventive and curative effort; and it cannot be too loudly proclaimed that this knowledge can only be obtained by systematic scientific research. The days of casual and statistical observations and dissertations have gone, and it is now universally understood that nothing will avail for the solution of pathologic problems except the undistracted work of trained agents provided with ample opportunities, facilities, and appliances. The recent history of malaria, to employ a new and expressive term, is a signal illustration of the dependence of sanitary and therapeutic endeavor on pathologic discovery. Laveran in 1880 furnished the key to the morbid processes which in malarious disease take place within the body by the discovery of the plasmodium malariae. Manson and Ross pioneered the brilliant investigations which have revealed one, if not the one, means by which this organism leaves the infected subject, lives and breeds in outer nature, thus compassing the communication of what must now be admitted to be an infective disease. It is interesting to observe how this knowledge is being at the present time turned to practical account, and how it explains and gives precision to methods of prevention and cure which had previously been resorted to empirically. Koch, in the Dutch Indies and German New Guinea, has been attacking the plasmodium within the human host, and claims, by destroying it in that phase or stage of its existence, not only to cure the individual, but to reduce greatly, or altogether abolish, the prevalence of malarious disease in the community. Sambon and Low, in Italy, are addressing themselves to the extrasomatic life of the parasite, and endeavoring by special contrivances and precautions to cut the morbid circuit outside the body. The results of the proceedings of Drs. Sambon and Low will be eagerly watched, as they will contribute an important aid to the solution of the question whether the *Anopheles* is the only medium of malarious infection, and if so, whether this occurs invariably by inoculation.

The South African war has forced into prominent and painful attention two diseases which, although they cannot be called tropical diseases, manifest themselves with special severity as regards incidence and fatality under tropical conditions—namely, enteric fever and dysentery. The theater of the war—the uplands of South Africa—cannot be classed, either as regards position or physical characters, as tropical. Malarious disease, the special and predominant product and index of tropical countries, is conspicuous by its absence among the causes of disability and death occurring in the British Army of South Africa. But the meteorologic con-

¹ An address delivered at the annual meeting of the British Medical Association at Ipswich, July-August, 1900. From advance sheets by courtesy of the *British Medical Journal*.

ditions which obtained during the early months of the campaign were most aptly described by the term "tropical." Sunstroke and sun fever were very common. I have endeavored to ascertain whether these cases were all or mostly cases of heat shock, and whether any considerable number of them presented the phenomena of heat fever—so-called "siriasis"—and, if so, whether these occurred in epidemics or appeared to be communicable. I regret to say that I have not succeeded in obtaining any information on these points. The cases which I have met with at Netley have presented a similar history and similar sequelæ to those received from India. Perhaps, when the medical history of the campaign comes to be compiled, some facts bearing on these questions may be forthcoming. I allude to the matter here and now in the hope of eliciting information.

That enteric fever existed in South Africa and was apt to prevail in South African towns and cantonments during the summer months was well known, and its appearance among the troops engaged in this war was fully anticipated; but the excessive prevalence of the disease in a country and climate with a reputation for exceptional healthiness has come as an unpleasant surprise. No doubt the circumstances and exigencies of warfare are mainly responsible for the heavy tribute of sickness and death which enteric fever has levied. War shares with famine the malignant power of enhancing the susceptibility to whatever infection happens to be present at the place and time.

Enteric fever has been in grim evidence during recent wars on the Indian Frontier and in the Egyptian Soudan; but malaria, cholera, yellow fever, and dysentery have on other occasions been stimulated into disastrous activity by war. So with famine: malarious disease, smallpox, diarrhea, dysentery, and relapsing fever have attended or followed it, and at the present time cholera and plague are raging among the famine stricken in India. The infection of enteric fever seems to be ubiquitous, portable, and peculiarly facile, and subtle; and perhaps the most urgent question of the hour is how to mitigate its prevalence in the British army, in which in times of peace it causes one-third of the mortality.

It is important to note that a very marked contrast exists between the ordinary incidence and mortality of the disease in temperate and tropical or subtropical countries—in England and Canada on the one hand, and in India and Egypt on the other. A similar contrast appears in the French army stationed in France and in Northern Africa. How much of this great excess is due to tropical conditions, topical and climatic, and how much to remediable sanitary defects it is not easy to say.

But, side by side with the excessive suffering of the army in India we are confronted with the remarkable fact of the immunity of the native population. Whether a similar immunity exists among indigenous races and habitual residence in South Africa is an interesting question. Evidence seems to indicate that it is so. The native immunity in India, though not absolute, is undoubted; its cause has not been satisfactorily ascertained. It has been attributed to habituation to minute dosage of the contagium, to protection conferred by attack during infancy and childhood, and to racial resistance acquired in the course of generations through both these influences. Some experiments by Freyer and others indicate that natives give positive reactions to Vidal's test; but more extended and exact investigations on this point are desirable. It is quite certain that the immunity of natives is not due to superior sanitary conditions. Whether a similar immunity—temporary or permanent—can be engendered in European subjects by a process of inoculation such as has been devised by Professor Wright, of Netley, and practised on a large scale among soldiers proceeding to the seat of war, is a question, the reply to which is awaited with eager anxiety. Some figures obtained from Ladysmith have been published by Professor Wright, which seem to show that some immunity is conferred by these inoculations, but though encouraging, they are by no means demonstrative. Similar procedures for creating an immunity against cholera and plague initiated by Professor Haffkine, have in India been attended with satisfactory results. But although a certain measure of preventive success has been obtained by these inoculations, the employment of them appears at present to be practicable and useful only as an emergent expedient in the presence of a serious outbreak; and the prevention of cholera, plague, and enteric

fever on a large scale must apparently be essayed on other lines and by other methods.

Dysentery has been very rife in the South African army, but the disease has exhibited mostly a mild type and been amenable to treatment. In some camps it has presented the aspect of an epidemic or infectious disease; but whether the infectiousness is apparent or real—due to common exposure to certain noxious conditions or to communication from man to man of some specific contagium—it is impossible in the absence of knowledge regarding the nature of the contagium or contagia of dysentery to say. The dysentery of war and famine is believed to be infectious, but notwithstanding much able and laborious research we have yet much to learn concerning the pathology and causation of dysentery. Imperfect conservancy, foul water, alternations of temperature, exposure, fatigue, and bad food, which are undoubtedly adjuvants if not factors of dysentery, have been in baneful operation in this war, and a new disease resembling dysentery has been described under the name of "dust colic." This seems to be a mucoenteritis caused by the swallowing with water and food of irritating particles of grit blown about by dust storms. The presence of the grit in the evacuations does not seem to have been sought for or found.

The persistence of plague in India and the appearance of the disease for the first time south of the equator—in Mauritius, South Africa, South America, and Australia—are events deserving of special notice. The disease has, during its present prevalence, confined itself mostly to warm and hot countries, and, though not exclusively a tropical disease, nor likely in the tropics to be at its worst when conditions are most typically tropical, it appears to find in tropical countries and circumstances the most favoring environment. It is curious to remark that, while in India natives appear to be readily susceptible to the infection of plague, Europeans, though not absolutely insusceptible, exhibit a comparative immunity—the reverse of what happens as regards enteric fever. This immunity is doubtless what I venture to call a sanitary immunity, due to a purer, personal, domestic, and social life, and perhaps to circumstances and habits rendering admission of infection less easy. This kind of immunity is also observable in some places—in Calcutta, for example—as regards cholera. How far an immunity of this sort is capable of being achieved as regards the infection of enteric fever, it is not easy to say. Certainly, it has not been accomplished as yet in India or Egypt. The Bermudas used to render the highest ratios of enteric prevalence and mortality, but within recent years considerable reduction of these rates has occurred through sanitary reforms in the matter, specially of water conservancy and sewage disposal. Similar causes have reduced the burden of enteric suffering in the French army of Algeria, and the power of sanitation has also obtained signal illustration in the banishment of beri-beri from the Japanese navy. Great Britain appears also to have acquired an immunity against cholera through sanitary reform and effort. These experiences are full of encouragement and hope.

Our concern is not only with exclusively tropical diseases, many of them strangely named, and imperfectly investigated and understood, which may be encountered and contracted in hot places where Europeans are compelled to reside for purposes of protection, administration, or commerce, and are not, as a rule, met with outside of the tropics. More important are those diseases, originally or essentially tropical, which may be disseminated by intercourse with the tropics, and may prevail for a time in extra-tropical localities in which they are not habitually present. And, finally, there are the diseases which are not specially tropical, but which are liable to be aggravated in prevalence or severity by tropical conditions. These three classes represent a wide field of research, and in addition interesting questions arise, as regards diseases which, common elsewhere, are rare or unknown in tropical countries.

The field of study thus presented has its scientific and humanitarian aspects, and its cultivation has become an essential part of the business of imperial administration. It embraces not only acute infections and the sequels or constitutional capacities resulting therefrom, but includes also those conditions affecting health and life which are vaguely designated as climatic, remediable only by adaptation, or which arise from sanitary defects or neglects capable of more easy amelioration. Hygienic improvements, personal, domestic, and social, have undoubtedly raised the standard of health

and the value of life in the tropics, and residence and service in hot countries offer fewer and less formidable risks than they did in times past. But behind the question of individual impunity looms the question of colonization or the continued vigor and vitality of the race when transplanted from temperate to torrid zones. The solution of these weighty problems constitutes the reason and purpose of our distinct sectional existence.

INTERRELATION OF PATHOLOGY AND BACTERIOLOGY.¹

By E. E. KLEIN, M.D., F.R.S.

Lecturer on General Anatomy and Physiology, Medical School,
St. Bartholomew's Hospital; President of the Section.

PATHOLOGY, in its analysis of the nature of the tissue changes, has been influenced, it is admitted, to a not inconsiderable degree by the progress made in bacteriology within the last two or three decades. Pathology, no less than, and in no way different from, other biological sciences, intent on answering the "what," as also the "why," asks not merely what is the intimate nature of a particular change and aberration of a tissue or organ from its normal or physiological state, but also, and in a higher degree, why this change, and what its cause? Why a particular alteration in one, another in another instance? Microscopic and experimental analysis have both been active in discovering some fundamental facts, but have left numerous gaps in this study, and it is by the aid of bacteriology—since it became, thanks to the foundations laid by Koch, an exact science—that these gaps are being closed up, or at any rate that the manner and method are indicated by which these gaps may, and probably will, be filled up.

1. *Inflammation*.—For more than a century inflammation, by the aid of the improved microscope, and by experimental work which had occupied a host of active minds and of great experimentalists, was being analyzed in all its elements: the part that the vascular system, that the tissues, that the nervous mechanism play in establishing the peculiar alterations constituting the phenomena of inflammation, suppuration, and their sequels; thereby an enormous number of facts were brought to light, by which the understanding of these particular aberrations from and return to the normal conditions became clearer, or were believed to have become well understood. It is now admitted, however, that with the exception of traumatic, thermic, and chemical agencies, the chief, if not the sole, cause of the changes of the vascular apparatus and the surrounding tissues constituting inflammation, inclusive, of course, of suppuration, are microorganisms, which, either by their chemical activity—producing substances which exert a toxic action on the vascular system or the tissues, or both—or by the toxic nature of the protoplasm of the microbes themselves, lead to the abnormal interaction between the vessels and the tissues, manifesting itself in the exudation of fluid and formed elements of the blood and the progressive or retrogressive changes of the tissue elements themselves.

It is one of the best-proved acquisitions in bacteriology that many microbes, either when growing and multiplying outside or within the tissues, produce toxins which in the tissues set up the phenomena of inflammation either locally or generally. This applies not only to those microbes which are specially and in the narrower sense connected with suppuration and abscess—for example, various species of pyogenic staphylococci, streptococci, and bacilli, but also to other specific pathogenic microbes like the diphtheria-bacillus, the tubercle bacillus, tetanus bacillus, typhoid bacillus. Koch's tuberculin, the diphtheria-toxin, the toxins of many other microbes produced in the test-tube, and then injected into the tissues produce typical inflammation. The same has been shown of the dead protoplasm of many microbes—for example, tubercle bacillus, cholera vibrio, *Bacillus pestis*, and others, as also of some ordinary saprophytes, namely, that the dead bodies of these microbes contain pyrogenic and pyogenic substances capable of producing typical inflammation.

¹ Introductory remarks made at the opening of the Section of Pathology, at the annual meeting of the British Medical Association at Ipswich, July-August, 1900. From advance sheets by courtesy of the *British Medical Journal*.

Another set of phenomena of which an explanation is supplied by bacteriology is one well known in the study of inflammation, that is the greater or lesser number of leukocytes in some inflammatory foci. It is well known that while some inflammations are characterized by copious transudations with few leukocytes, others on the other hand are associated with copious accumulation of leukocytes, as in suppuration. The phenomenon of chemotaxis seems to offer a good explanation for these differences, that is to say, while some microbes or their toxins powerfully attract leukocytes from the blood and connective tissues, others have no such effect or possess even the reverse, namely, negative chemotaxis. In a similar manner Pfeiffer first classified the effects of chemical substances on lower organisms.

2. *Necrosis*.—The most valuable and earliest observations were those of Roux and Yersin, showing that the toxin produced by the diphtheria-bacilli has a powerful necrotic action on the tissues. The further demonstration of the actual presence of the toxin in the diphtheric membrane supplied at once the simplest and most feasible explanation of the necrotic condition of the mucous membrane in diphtheria, namely, the multiplication of the diphtheria-bacilli at a particular locality—be it the fauces or larynx, or trachea or bronchi, or any other membrane—causes the production of the toxin, which in its turn causes the inflammation and further the necrosis of the membrane. But this action, namely, localized inflammations leading to gradually progressive necrosis of the tissue elements, is not peculiar to the diphtheria-bacilli and their toxins, for it is almost a common character of many if not most pathogenic microbes; it is observed in connection with almost all hitherto known pathogenic bacteria, tubercle, glanders, leprosy, pseudo-tubercle, pathogenic cocci, and bacilli of various kinds. It is this progressive necrosis of the tissue following the typical symptoms of inflammation: congestion, stasis, diapedesis, and emigration of leukocytes which is observed, granted the necessary number and virulence, as the effect of the action of many pathogenic microbes, inasmuch as at a particular locality—primary as well as secondary foci—so long as their multiplication proceeds and their toxins are being produced in increasing amounts the necrosis of the tissue spreads into larger and larger areas. In nonmicrobic inflammations, on the other hand, this necrosis is local and circumscribed, being due to the direct action of the noxious agent—thermic, chemical, or traumatic—and its action is limited to the part actually attacked or its immediate surrounding. The necrosis itself appears in both series, however, of the same essential character, namely, coagulation of the protoplasm of the tissue cells, inclusive of the vessels themselves, and a gradual disintegration and destruction of the cells as also of the intercellular ground substance. These phenomena have been well observed in the case of a number of pathogenic microbes. Another not less important set of appearances associated with the necrotic change caused by bacteria is the secondary leukocytosis and suppuration; and for this the chemotactic action that the necrosed tissue exerts on leukocytes, attracting these for one reason or another, probably as scavengers and removers, offers a ready explanation.

3. *Specificity of Cell Secretions*.—Until recent years it was generally considered that a specificity of cell secretions is one of the fundamental phenomena of the physiologic or normal tissues. Behring, Kitasato, Brieger, Roux, Ehrlich, and many others have, however, shown that under the activity of many pathogenic bacteria and their toxins in an affected body a curious and important series of secretions on the part of the cells of the tissues takes place which is as specific as those others associated with the normal life, I mean, the production of specific antitoxins and the production of specific agglutinins. It was further shown that not only under the stimulation of the cells by bacteria and their toxins are those specific antitoxins secreted, but that organic substances like abrin, ricin, venin, are capable of stimulating the cells to a like production of specific antitoxin. Moreover, quite recently a further highly interesting series of facts has been brought to light, namely, that particular tissue taken from one animal body and introduced into another causes a specific reaction, showing itself in this that the living cells of the latter produce under the particular stimulation substances specifically acting on the particular tissue that has caused the stimulation. Illustrations:

a. Injection of ciliated epithelium of the trachea of the ox

into the peritoneal cavity of guineapigs produces a definite change, inasmuch as in a second injection of similar epithelium the ciliary movement is stopped and the cells destroyed in a markedly shorter space of time than in a normal animal; the same action takes place *in vitro*: here the same difference between normal serum and specific serum is demonstrable.

b. Metchnikoff shows that rat's spleen injected into guineapigs produces serum which is capable of agglutinating and dissolving leukocytes of the rat.

c. Funck shows that repeated intraperitoneal injections of rabbit's spleen into guineapigs in ascending doses produces a serum which *in vitro* has specific cell-destroying—cytolytic—action on both lymphocytes and polynuclear leukocytes of the rabbit, whereas red bone marrow of rabbit produces when administered in the same way a serum which has a greater action on polynuclear leukocytes than on lymphocytes.

From these experiments it is clear that by certain pathological processes the tissue cells are capable of being so altered that their secretions assume a specific action not possessed by them before.

THE TEACHING OF PHARMACOLOGY.¹

By WALTER G. SMITH, M.D.

President of the Section.

THREE lines of inquiry which have been followed in the past and must be pursued in the future, namely:

1. Experiments on lower animals.
2. Statistical observations of the results of treatment, and
3. Individual observations at the bedside.

TEACHING OF MATERIA MEDICA.

The rise and growth of the science of pharmacology, which was founded by Bichat and Magendie early in the century, has made it plain that all correct appreciation of the mode of action of drugs must be based upon physiology and pathology. The new departure has gradually leavened our conceptions of therapeutics, and renders the teaching of this branch alike more intelligible to the student and more satisfactory to the teacher. Comparing the teaching of materia medica and therapeutics thirty years ago with the present time, three features stand out prominently:

1. The retrogression of descriptive materia medica in its restricted meaning.
2. The establishment of special courses in practical pharmacy at the medical schools, conducted in suitable laboratories.
3. The development of pharmacology in its present acceptance—that is, the scientific investigation of the modes of action of drugs.

I protest against undue neglect of what may be termed old-fashioned materia medica—that is, description of the *essential* properties and chemical nature of drugs, so far as these elucidate the action of the remedy or its relations to prescribing. A modern course of lectures on materia medica should most certainly be founded on the bed-rock of pharmacology, that is, physiology; but there is still room—nay, I think, necessity—for practical demonstration of the physico-chemical properties of drugs, and we need not even be ashamed of inculcating the utility of some familiarity at least with the pages of the *British Pharmacopoeia*, which it is the fashion of some to despise or decry.

With a little thought and trouble numerous simple experiments, chiefly chemical, can be shown in illustration of the more important physiologic and therapeutic properties of drugs. General principles can be laid down, alliances pointed out, and broad features sketched, which connect together large numbers of drugs, into the individual details of which it would be wearisome and a waste of time to enter.

Take, for example, antipyretics and their mode of action; or the local action of astringents and caustics, experimentally illustrated by the reactions of various acids, and metallic salts upon solution of albumen. Or, again, the group of "aromatic compounds," where it is possible to give a brief but comprehensive survey of the general chemical and physiological relations of the subdivisions of this great group—namely, hydrocarbons, phenolic compounds, acids, and nitrogen derivatives (alkaloids, etc.). And in this aromatic group, which includes the antipyretic drugs, there is abundant opportunity for drawing attention to many interesting points in illustration of the connection between physiological action and chemical constitution.

PHYSIOLOGICAL ACTION AND CHEMICAL CONSTITUTION.

Since the properties and motions of molecules which determine physical properties depend upon the motions and properties of atoms which determine chemical reactions, the same common laws must govern both physical and chemical phenomena. And no one can doubt that the properties of the most complex compounds depend upon, and are intimately correlated with, the properties and configurations of the atoms and molecules of which the aggregates are built up. Bit by bit—here a little, there a little—we are gathering the kind of material which can best help us to gain insight into the principles of therapeutics. The problems of therapeutics, and for that matter of all biology, are, at the root of things, essentially chemical or physico-chemical, in so far as we are at all able to interpret them or refer them to general laws. Different effects produced upon the senses of smell, taste, and sight are coincident with differences of arrangement in the molecules of the respective compounds which are built around a common nucleus.

Innumerable difficulties still await an answer, for example, Why should saccharin, which is an "ortho" compound be so sweet, while the "para" compound is devoid of sweetness? Still we can assert that great progress has been made in expressing the laws of mixture, combination, solution, dissociation, and chemical transformation on a generalized basis, and chemistry and chemical physics are gradually being brought under the sway of dynamical laws.

PHYSICAL CHEMISTRY AND THERAPEUTICS.

We have to take into account not only the number and kind of atoms in the molecule, and their interior arrangement and grouping (constitution), but certain physical properties of compounds previously inexplicable have found their explanation in another development of chemical theory which has proved extraordinarily fertile. The doctrine of the spatial configuration of the molecule has done much to elucidate the difficult problems of isomerism in organic chemistry, and we cannot doubt that it will shed light upon chemical transformations occurring in the organism.

A PROTEST.

The flood-tide of discovery of new synthetic chemical remedies has, together with a few treasures which have risen on its crest, also washed on shore much rubbish of a pseudoscientific sort. Are we not daily worried with samples, and with advertisements and circulars from eagerly competing firms, announcing new drugs or novel combinations, which I fancy, are used chiefly by those who do not know how to employ the old ones? Scarcely are they advertised once before they are elbowed away by importunate newcomers. The advertisement is headed with an enigmatical name, standing over an appalling chemical formula, and probably ornamented with a structural or graphic diagram. All this is backed up by a plausible show of original experimental work, and ends with a "full literature." And not only are we plagued with innumerable circulars which choke our waste-paper baskets, but we are tormented during our consulting hours at home by the visits of smooth-tongued touting agents of many of the large firms.

This most objectionable practice is on the increase. It should, in my opinion, be stamped out by the medical profession, and I avail myself of this public opportunity to protest against it.

¹ An address delivered to the Section of Pharmacology and Therapeutics, at the annual meeting of the British Medical Association at Ipswich, July-August, 1900. From advance sheets by courtesy of the *British Medical Journal*.

SOME PROBLEMS IN RURAL SANITATION.¹

By JOHN C. THRESH, M.D., D.Sc., Etc.

Medical Officer of Health, Essex County Council; Lecturer on Public Health, London Hospital Medical College; President of the Section.

THE growth of large manufacturing centers with the influx of rural laborers into towns, and the general neglect of purely agricultural pursuits, must in this country produce some marked effect. That this effect will neither conduce to increased health nor longevity can scarcely be denied; hence it is a result which we must deplore. The country has already reached a condition in which the population far exceeds that which can be fed by its produce, and the condition is being aggravated year by year by the increasing population and continuous neglect of agriculture, and I am afraid will continue until we receive a rude awakening, an awakening which in all probability will stagger humanity.

Our purely rural population is slowly decreasing, our urban population is rapidly increasing; therefore year by year the feeding problem becomes more serious. This is a fact so well recognized that its very familiarity is producing contempt. It is well, however, that we should from time to time be reminded of the fate upon which we appear to be almost blindly rushing. Sanitary improvements, unfortunately, tend only to aggravate the evil and hasten on the day of reckoning. So much attention has been devoted to urban sanitation that the town dweller enjoys now many advantages not possessed by those who remain in the country, advantages which tend to prolong life, increase health, and, generally speaking, make life better worth living. For example, in most of our towns every house is efficiently drained and abundantly supplied with pure water, rendering it possible, with the minimum of trouble, to keep a house and its surroundings sweet and clean, and therefore healthy. In our villages and rural districts nuisances from the improper disposal of filth abound on every side, and the water-supplies too often are unsatisfactory in quality as well as in quantity.

Land is going out of cultivation and decreasing in value, yet it is often impossible to obtain a small quantity to effect sanitary improvements. Let a plot be required in order to provide cottages with ground upon which to dispose of the slops and house refuse, or for the erection of better houses for the laborer, or for the erection of an isolation hospital, and it is often almost impossible to obtain it. Landowners refuse to sell small areas for such purposes, yet, in my county at least, farms are sold at ridiculously low prices, and the speculator who purchases, recognizing the demand for small plots, promptly cuts up the farms and sells the land at an enormous profit. The dog-in-the-manger policy so common among landowners and their agents I cannot account for, but it is a fact which is well recognized and deplored.

How to bring back people to the land is one of the greatest problems of the age. It is far too large a subject for me to dwell upon, but I am convinced that one of the chief requirements for restoring prosperity to our rural districts is increased facilities for acquiring small areas of land for sanitary improvements. Some years ago one of my sanitary authorities succeeded in acquiring a small amount of land behind a group of rural cottages which had no gardens. A portion was allotted to each cottage, the conveniences, which had been near the back doors, were removed to a safe distance, and there was sufficient ground to permit of the slops, house refuse, etc., being disposed of without causing any nuisance, and the old defective drains with their accompanying Dutch nuisances were abolished. Twice since the same authority has made repeated efforts to carry out similar improvements in other places, but the necessary land could not be obtained. With a sufficiency of land adjoining or near each house, the necessity for sewers in most of our rural districts would be avoided.

In compact villages, urban in character, drains and sewers, I am afraid, still remain a necessity. The expense of such drains and sewers would in most cases be willingly borne, but the cost of obtaining sufficient land upon which to dispose of the sewage is one of the most frequent excuses for

not carrying out such improvements. Land not worth £5 per acre suddenly acquires a value of £100 or more per acre, and this, together with the trouble and worry consequent upon the adoption of any scheme of sewage disposal prevents the adoption of such schemes. If the numerous experiments now being made on bacteriologic lines result in the discovery of some simple process requiring but little land for disposing of sewage, a great advance will be rendered possible in rural sanitation.

The supply of water to our cottages is even a greater difficulty. Sanitary authorities are not only averse to the expenditure necessary to provide a public supply, but too often also averse to causing landlords to provide such a supply when it can be done at what is defined by Act of Parliament as a reasonable rate. The effect of such a policy has been well exemplified recently in a rural district in which I am interested. A group of cottages derived water from a brook, one of the tributaries of which, at a higher point, received a certain proportion of the slops from the drains of a village. A case of typhoid fever occurred in the village, and about a month later an outbreak of typhoid occurred in the group of cottages and resulted in several deaths. Some five years before I had endeavored to get a proper water-supply for these cottages, but an influential member of the council opposed this as being unnecessary. Notwithstanding my predictions of future trouble, the resolution to call upon the owner to provide a proper supply was lost. I only hope the lesson taught by this epidemic will not soon be forgotten. The cost to which the sanitary authority and others have been put is far greater than would have been required to provide a supply of good water. The multiplication of dairy farms also is increasing the necessity for an abundant supply of pure water in rural districts. Another very important requirement, I might also say the vitally important requirement, is decent cottages for our rural laborers. The effect of the present defective accommodation upon the mental, physical and moral well-being of the inhabitants is too well known to need repetition. The housing problem is of importance not only to the rural laborer but to the whole country, and should be treated as a national problem.

WORK OF THE SURGICAL SECTION.¹

By HOWARD MARSH, F.R.C.S.

Surgeon and Lecturer on Surgery, St. Bartholomew's Hospital; President of the Section.

ON some previous occasions so many papers have been accepted for reading that many valuable contributions could only be hurried through in abstract, and no discussion was possible. This was unsatisfactory to all concerned. On the present occasion the object has been to cut the garment according to the cloth; in other words, to adjust the number of papers to the time that is available, so that each may have a fair hearing, and be fully discussed. I anticipate that all who are present will regard this as the proper method. Two set discussions have been arranged on subjects, both of which I feel certain members will regard as well worth their attention; subdiaphragmatic abscess is no doubt a somewhat rare condition, yet it may occur in the practice of anyone. It is highly dangerous to life, and both in regard to diagnosis and treatment it presents difficulties of a very grave and embarrassing order. As the subject will be introduced by Mr. Godlee, and discussed by those whose names are a guarantee of their knowledge and sound judgment, I am sure that valuable information will be forthcoming.

The subject of fractures belongs to a different order. It is so old and familiar that it may appear at first sight too hackneyed and barren to be worthy of your notice. On second thoughts, however, I believe that it will be felt that the opposite is really the case. Long a mere matter of routine the treatment of fractures has lately felt the influence of modern advance in other departments of surgery. The Röntgen process secures an accuracy of diagnosis which formerly was often impossible. The aseptic method makes

operative interference safe, so that when necessary it can be adopted without hesitation, and it has become obvious that to secure the best results treatment must be applied not only to the fractured bone itself, but to the neighboring joint and the muscles and other structures of the limb.

THE TREATMENT OF WOUNDED AT SEA.¹

By INSPECTOR-GENERAL BELGRAVE NINNIS, M.D., R.N.

THE great war—now we trust nearly at an end—has directed special attention to its three subdivisions, namely, medicine and surgery, in relation to the services, and ambulance in connection with both, and likewise with civil life, particularly in large towns. A goodly supply of papers on these and kindred subjects will claim your attention, but I notice with regret the absence of one on a subject which I consider would be well worth the trouble of writing—namely, on the means at the disposal of the naval medical officer for the treatment of the injured on board a man-of-war, more especially during an action.

Experience of the medical press, extending over a somewhat lengthened period, has left the impression on my mind that there is a belief amongst our brethren in civil life that the naval medical officers, taken as a class, are either behind the times, professionally, or are credited (from lack of zeal) with neglecting to avail themselves of modern discoveries, both in medicine and surgery, and that this due in great measure to absence for lengthened periods from the schools. It is true that, from the very nature of his calling, the naval medical officer is away at times for a period of 3 or 4 years; but, on the other hand, it should be borne in mind that there are sick in other countries besides Great Britain, and studying familiar diseases under different climatic conditions, or cholera, yellow fever, plague, and other diseases in countries where they are endemic, with the methods of treatment adopted by those who have lived the whole of their professional life in their midst, modifications in some ordinary operations and substitution of new ones amongst the profession abroad is surely worth something. Operations at foreign hospitals can always be attended, and practitioners and hospital surgeons are, in my experience, ever willing to answer questions, and to show you their cases where possible. I have not said anything about his own patients, which, if his ship is a large one, supply him with a heterogeneous practice, in addition to a capital operation occasionally.

The essentials of a fighting ship may be said to comprise the largest percentage of armament, offensive and defensive, combined with capability of rapid motion and a steady platform. So far as our present knowledge goes, these conditions can only be obtained at the expense of space; or, in other words, the more effective a fighting machine the ship is, the less space is available for quarters and accommodation for the sick. Necessary as light and fresh air are to all of us, in the case of the sick on board ship, it will easily be understood that this necessity is more urgent. But light and fresh air can only be obtained in sufficient quantity above the water line, and to place the sick quarters above the water-line, amidst the hurly-burly of a sea-fight, traversed by projectiles and wrecked by exploding shells, is of course out of the question, even supposing that sufficient space could be spared. The alternative is treating the sick and injured below, which means a limited amount of fresh air, and that almost invariably supplied by mechanical means, artificial light, rapidly deteriorating atmosphere, and the by no means unlikely intrusion of a torpedo, or of the ram of a neighboring ship.

It will doubtless be said that this condition exists only during war time, and that, under ordinary circumstances, plenty of space could be found on deck. Sufficient accommodation is, as a matter of fact, already set apart for the treatment of the sick, with ample light and fresh air, cots, and other fittings of recent and constantly improving designs, and in some cases electric light; but it must be remembered that for the reasons previously mentioned these peace arrange-

ments must be vacated in war time. As permanent quarters for the sick on board a fighting ship, situated in such a position as to be freely supplied with fresh air and light, are practically an impossibility, it follows that the fitting up of apparatus, and the means of utilizing modern inventions are likewise practically impossible, and therefore the naval medical officer cannot avail himself of their use.

In fact, the naval medical officer is not to be judged by the ordinary standard. He works under great disadvantages. Take an ordinary operation. A moving patient on a moving table, a moving operator standing on a floor changing its slope laterally and fore and aft, assistants automatically altering their positions in relation to the patient, in retaining the upright position or their equilibrium; tracheotomy by the light of a candle or lamp, the patient being in a cot, or possibly in a hammock; hernia to be operated on, possibly during bad weather, for it is the nature of things that on board ship accidents should most frequently occur when there is most motion, and the decks are wet and slippery; fractures to be retained in position under the same adverse circumstances. As for lack of zeal, a collection of the novel splints and appliances to be found on board ships on return from out-of-the-way foreign stations would testify not only to the zeal of the naval medical officer, but also to his resourcefulness, for, be it remembered, he cannot send into the next street for a second opinion, nor to the instrument maker for special appliances. It is, I believe, intended in the future to supplement fleets and squadrons in war time with hospital cruisers, not merely transports for the injured, but veritable floating hospitals with steam power and fittings and appliances up-to-date. During an action these ships would keep out of range, but sufficiently close to collect the wounded when the fight was over, and sailing under the regulations of the Geneva Convention would be free from molestation or capture.

Paralysis of Children.—Virgil P. Gibney (*St. Louis Courier of Medicine*, May, 1900) advocates rest and quiet for the muscles and joints in the early stage of paralysis in children instead of the attempts at massage and use of the parts that have been so common. Brisk counter-irritation to the spinal column in conjunction with absolute rest of the lower extremities he finds of excellent effect. The time for electricity and massage is later. He personally believes that it is better to protect the joints from strain during the first year because lax joints will become less lax and laxity of those tissues will not recur; rest encourages the nutrition of the parts, the circulation is improved and the little strength remaining in the paralyzed or partially paralyzed groups of muscles is not overtaxed. In his opinion in all such cases the surgical problem is not how the tissue is repaired, but how the greatest amount of relief may be afforded. Relieve deformity by traction if possible, but if not, then section, subcutaneous or open, should be a favorable resort; he advocates reinforcing palsied muscles by causing a portion of a healthy muscle to assume its function. Quite recently he grafted into the posterior tibial one-half the tendo-achillis and one-half the common extensor, shortening the tendo-achillis at the same time. This boy will be able to walk and with scarcely a trace of deformity. [M.B.T.]

The Treatment of Appendicitis.—J. J. Buchanan (*Pennsylvania Medical Journal*, July, 1900) strongly insists that, after the purge given on the first access of symptoms, no effort be made to empty the bowels except by enemata. He is confident that many cases of ulcerative and gangrenous appendicitis, which, if left to nature, would be walled off by protective adhesions of omentum and intestine and thus become abscess cases, are converted into cases of general peritonitis by the rupture of the delicate adhesions and the actual distribution of septic fluids through the active peristalsis set up by the persistent exhibition of saline purgatives. He lays it down as a rule that every patient, not the subject of other organic disease, who has had a single well-marked attack of appendicitis, should have the appendix removed. To his mind, the important point in operating on all abscess cases, is never to open the general peritoneal cavity and the abscess simultaneously; when one is opened, the other should always be closed and protected. [M.B.T.]

VOL. VI, No. 8

AUGUST 25, 1900

\$3.00 PER ANNUM

A Step Forward.—The Board of Health of the city of Trenton, N. J., has demonstrated its appreciation of modern sanitary requirements by the proposition to include pulmonary tuberculosis among the notifiable diseases; for how can a preventable disease be stamped out unless health-authorities with ample powers and intelligent direction are informed of its existence and the places where it thrives? Good will be accomplished also by the action of the same Board in making spitting on the street and in the public places a punishable offence. The way to eradicate tuberculosis is to prevent it, and light is now penetrating into dark places.

The Honorary Fellows of the Royal College of Surgeons.—We have already called attention in our news columns to the recent centenary meeting of the Royal College of Surgeons, England, and to the award of the honorary diploma of fellowship to Dr. W. W. Keen, of Jefferson Medical College of Philadelphia; Dr. Robert F. Weir, of Columbia University, New York; Dr. J. Collins Warren, of Harvard University, Boston; and Dr. William S. Halsted, of Johns Hopkins University, Baltimore. The Canadian Surgeons honored were Sir W. H. Hingston, Dr. T. G. Roddick, of Montreal, and Dr. J. H. Cameron, of Toronto. Honorary degrees were also awarded to eminent medical men from nearly all civilized lands, including Germany, France, Austria, Italy, Russia, Sweden, Norway, Denmark, Spain, and to many eminent British surgeons both at home and in the colonies.

The American profession rejoice in these honors so worthily bestowed and accept this as an additional evidence of the friendly feeling which has so long existed between the profession in England and America. The presence of the Prince of Wales, of Lord Salisbury, and Lord Rosebery at the exercises and the banquet indicates that the world of politics and society is beginning to recognize the services of the medical and surgical profession, and in this all medical men rejoice. We have previously criticised the action of institutions and bodies of learned men in conferring honorary degrees upon those who have no real claim to them from any special knowledge of the subject which the degree was originally supposed to imply, and we cannot help feeling that when the honorary fellowship of the Royal College of Surgeons is conferred upon men however eminent, who have no

knowledge of the subject of surgery, that it loses a little of its special value. Honorary degrees are becoming entirely too cheap and it is often impossible to tell from a man's numerous titles whether he is really a learned man, a gentleman and eminent scientist, or an eminent quack and Christian scientist.

Excessive Damages.—In the Court of Common Pleas of this city, Judge Pennypacker recently set aside a verdict for \$47,000, which had been rendered in favor of the plaintiff in the case of *Waters vs. The Atlantic Refining Co.*, and ordered a new trial. The plaintiff, a boy aged 13 years, was an employe of the company, and while at his work lost his eye-sight by accidentally splashing some acid into his eyes. The learned judge, in his decision, held that the earning capacity of the plaintiff had not been satisfactorily demonstrated to the jury, and therefore that the jury had been left to find this very large verdict without information as to facts which should be of fundamental importance in enabling it to arrive at a just conclusion. In another case the Supreme Court of this State, according to Judge Pennypacker, had reversed a judgment for similar reasons, holding that it was the duty of the plaintiff to show his earning power and to give such evidence of his business habits and past earnings as would afford a proper basis for a verdict. It is an error, according to the court, to leave the damages to be determined by the uncontrolled discretion of the jury. This verdict for \$47,000 in favor of young Waters is the largest ever rendered in the Philadelphia courts in a suit for personal injuries.

This question is, of course, a purely legal one, yet it has interest for those physicians who are called upon to give advice and expert testimony in such cases. It is a frequent experience with such physicians that litigants in these damage suits entertain extravagant ideas of the amounts to which they are entitled, and that they are not satisfied unless their expert witnesses share these ideas with them. It is, of course, not the province of experts to attempt to fix the value of personal injuries, but it is difficult for litigants to see this point, and they are likely to expect physicians to bear witness to the alleged justice of altogether unreasonable claims. This is not a little embarrassing at times and, moreover, prevents experts from giving advice that would tend to effect a fair settlement outside of the courts. This de-

cision of Judge Pennypacker will remind litigants that they have to deal not only with juries, but also with the judges.

The Dangers of Trailing Skirts.—*The Springfield Republican* is authority for the statement that Dr. Casagrandi has recently read a paper on this subject before a medical association at Rome. Dr. Casagrandi stated that he had employed a number of women, wearing long skirts, to walk for one hour through the streets of the city and, after their promenade was over, he had taken their skirts and submitted them to a careful bacteriologic examination. He found on each skirt large colonies of noxious germs, including those of influenza, tuberculosis, typhoid fever and tetanus. Numerous other bacilli were also well represented on each skirt. Dr. Casagrandi maintained that in view of these facts, women, and especially mothers, should at once stop wearing long skirts, and the other members of the congress unhesitatingly expressed the same opinion and passed a resolution to this effect.

That women should willingly subject themselves to the filth, say nothing of the possible dangers of trailing skirts, has long been a wonder to sensible people who are acquainted with bacteriology. For street wear they certainly cannot be considered in any sense either cleanly or hygienic. However, we cannot expect reform in this matter without those who set the fashions can be influenced, for women are bound to be in the fashion regardless of any ordinary considerations. There is some encouragement in the fact that at present bicycle skirts and golf skirts are in vogue, and we hope they will become still more popular, for while we are not aware that any previous scientific investigations have been undertaken in this line any well-informed medical man could have readily predicted the results of such investigation.

Reform in the Milk-Supply of Large Cities.—The question of milk-supply of large cities is of great importance, particularly during the hot season. The large mortality among infants and children during summer months is dependent to a very considerable degree on the milk-supply, and any effort to procure a safer food for the public, and particularly for young children, deserves the attention of the medical profession and of all interested in sanitary matters. Dr. Nietner discusses this question at some length in the *Berliner klinische Wochenschrift* for April 16, 1900, and especially calls attention to the efforts which have been made for the improvement of the milk-supply of Berlin by W. Helm, one of the city sanitary engineers. He advises the adoption of a method which it is stated has been used for some time in Copenhagen. The milk is collected at the source of supply and pasteurized before shipment; immediately after it is cooled nearly to the freezing-point. By this method the milk remains entirely fresh and

has the taste of fresh milk and the cream rises in exactly the same way as with ordinary milk. The milk which is thus prepared is put in cans sterilized by steam and is kept in a cooler until ready for shipment. In summer a certain amount of frozen milk is added, the amount of this milk-ice depending upon the distance which it is to be transported and the temperature at the time of shipment. This keeps the milk cool until it reaches its destination. It is stated that this method is applicable in all towns which serve as milk-supplies of large cities when the daily shipment amounts to 7,000 liters, and the cost is only one-half pfennig (about an eighth of a cent) per liter. Nietner believes that in future milk will not be shipped directly from the producer by the railroad to the milk dealer, as is now the case, but will be sent to a central pasteurizing and cooling plant, where its quality will also be tested. Under the present method of shipment much of the milk while not sour is considerably influenced by bacteria before it reaches the consumer. By the method just described milk can be preserved for any length of time. These establishments for pasteurizing milk have lately been introduced in many of the suburban towns in the vicinity of Berlin, and others are in process of construction. Nietner states that from personal visits he found everything with regard to appearance, smell, and taste quite ideal. The method has attracted attention not only in several parts of Germany, but also in Austria, Switzerland, Russia, and Holland, and in these places plants are in process of construction.

This method of securing an absolutely trustworthy milk-supply for large cities is worthy of introduction into American cities. At present it is impossible to obtain milk suitable for the use of sick people and particularly sick children without great trouble and expense, and it has been repeatedly shown that epidemics of various diseases frequently arise from an improper milk-supply. We hope that this method will come to the attention of all interested in the sanitary improvement of our cities and towns.

Experimental Studies of Intestinal Functions; Penetration of Bacteria; Electric Stimulation.—

It has been generally supposed that the intestine, like the skin, is not permeable by bacteria; but later researches by different observers have shown that the fluid of hernial sacs in 33.9% of cases contains germs, and this discovery led to the idea that bacteria were capable of passing through the living intestinal wall. The inexactness of the researches, however, left some doubt regarding this most important question, and we are indebted to Buchbinder (*Deut. Z. f. Chir.*, 55. Band, p. 458 to 556) for an elaborate series of experiments on the lower animals by methods of research which seem scarcely to admit of error, as they allow direct inspection of the intestine during the experiment. His method consists in bringing a portion of the intestine

outside of the abdominal wall and by means of a steam spray, keeping it moist and warm; and he definitely demonstrated that as long as the walls of the intestine were intact it was impossible for the bacteria to pass from the lumen to the serous surface of the gut, and further that when gangrene had set in the bacteria "grew through," as it were, rather than passed through as the result of a transudation. Also by this method of experimenting, the demonstration of the mechanism of the strangulation of a hernia was well shown through having the intestine so easily inspected. Another discovery of almost equal importance with that regarding the penetration of bacteria was the effect of electrical stimulation on the intestine. It was shown that the effect of the faradic current on the living intestine of animals, in the production of the so-called "ascending contraction," could be reproduced in man. That is, when a faradic current is applied to the living and normal intestine for about two minutes, a ring of contraction is produced which extends *upwards* for two centimeters and the intestine returns to its normal state as soon as the current is discontinued. By this simple procedure the surgeon has a safe method of determining the direction of the gut when peristalsis is not present. Again it was demonstrated that the intestinal wall when deprived of its vitality does not give this characteristic reaction. Indeed, in every case in which electrical stimulus failed to cause the contraction, gangrene invariably followed. Therefore, in cases of strangulated hernia, after the constriction has been relieved for several minutes, and the intestine does not respond to the application of the faradic current, it should be regarded as having permanently lost its vitality and should be treated in accordance therewith.

These results obtained by Buchbinder after a great deal of labor and thought are most interesting and of great practical importance. They touch questions which the busy surgeon is frequently called upon to solve and which have not been altogether easily settled. We trust that further investigation may prove that his conclusions are correct.

Burial Alive.—The periodical agitation of this subject is to be expected. It appeals to the morbid imaginations of those persons who cannot find things shocking enough above ground. The highly neurotic individuals who lie awake at night in dread of being buried alive, have now come forward once more, and are demanding a charter for a society the object of which is to make sure that they are properly despatched before they are entombed. This betokens a bad state of nerves, and one that must make life little less worth living than actually being buried alive. To live in constant apprehension of what may never occur is a well-recognized symptom of neurasthenia.

The proposed society—which most appropriately is to be located in New York—will demand that a series of

highly sensational tests be made in the case of every corpse. These tests include two or more incisions in an artery; exposure of the palm of the hand to the flame of a candle; holding of a mirror or crystal to the mouth for a sign of respiration; the use of a hot iron on the flesh without production of a blister; mortuary chapels for retaining the body until signs of decomposition occur. The last test seems to exclude the necessity for all the others, and is so simple and practically so almost universally observed already, that there does not seem to be much necessity for getting a charter or a patent-right for it. We would suggest as a valuable test the use of a clinical thermometer.

The estimable gentlemen who are back of this scheme publish an apocryphal list of premature burials. Some of these tales are a few centuries old, and smell more of the cloister than they do of the tomb. We have no knowledge of a well-authenticated case of live burial, and believe that the probability of such an occurrence is infinitesimal. Even putting aside the objections of the so-called dead person, there would be the physicians and other attendants to be deceived before such a burial were possible. Moreover, there is no trance-like state known to science that thus simulates death. We commend all timid neurasthenics to soothe their nerves, and if they need a positive guarantee that they will not be buried alive, let them direct their bodies to be cremated. This is both sure prevention and good hygiene.

Recent Work on Epilepsy.—Dr. L. Pierce Clark, first assistant physician to the Craig Colony for Epileptics, at Sonyea, N. Y., has just completed, in the *Journal of Nervous and Mental Diseases* (June and July, 1900), a valuable digest of recent works on epilepsy. The literary field thus surveyed is very extensive, and much that is interesting and instructive is portrayed, but the amount of new truth brought to light is rather meager and is a melancholy reminder of how little we yet know, or seem likely soon to know, of the real mysteries of the sacred disease. Dr. Clark's opinion that the epileptic is foredoomed to die of *status epilepticus* will at least convey a novel idea to many observers. It seems to us a somewhat extreme statement. In his conclusions Dr. Clark says that the etiology and pathology of epilepsy seem as far as ever from being solved. The study should be along lines of physiological chemistry and physiological psychology. Thorough investigation must be made also of the predisposition in order that the immense number of alleged excitants can be classified and their values as causes determined.

The manifestations of epilepsy, Dr. Clark finds, are daily becoming more numerous, but this, we judge, is simply due to more active clinical study of the disease. This variety of clinical manifestations does not in itself throw any new light on the nature of the disease. The essential phenomenon or pathognomonic sign of epilepsy is still somewhat of a will-o'-the-wisp. It is not

"loss of consciousness," because this is not constant, although some disturbance of consciousness is probably always present; hence, after all, the affection of this state is perhaps the best criterion. Dr. Clark holds, with the majority of neurologists, that the sensory and motor symptoms can not well be separated. Studies of "signal" symptoms, *i. e.*, the primary muscles attacked and the order of invasion of muscular groups, have not helped to solve the problem of epilepsy as much as was once hoped; but here, it seems to us, Dr. Clark would have done well to point out that these signal symptoms are of immense practical value in brain surgery. Psychical equivalents and pure psychical epilepsy are so loosely studied as yet that their true nature is not fully understood. The possibilities for the careful study of temporary epileptic delirium and the light it would throw upon the insanities, were never greater than today. The grouping of epileptics in colonies offers unrivalled opportunity for the study of the disease.

Organic Hysteria.—Of all the purely functional disorders which result from trauma it must be conceded that hysteric affections are probably the commonest and the most puzzling. That they are frequently disguised under assumed names in our courts is a matter of common observation. The prejudice against the term "hysteria" is not confined to the medical profession, but is entertained widely by all persons, and especially by the ignorant classes, from whom largely our juries are recruited. To concede to such a jury that a claimant is hysteric is believed practically to give away the case. That there is good reason for this belief is obvious. Recently, in a Camden court, a man secured a verdict for \$5,000 for a typical hysteric paralysis of an arm caused by a shock of electricity from a low-hanging arc lamp, but the lawyer in the case had evidently succeeded in convincing the jury that the muscles and nerves had been destroyed by the mysterious current. Soon after, in a Philadelphia court, a woman with an almost identical paralysis caused by a blow from a falling sign, failed to receive damages because apparently it was successfully demonstrated to the jury that the affection was merely hysteria. These two cases illustrate the subject perfectly. They prove that there is something in a name when damages are concerned. They also show that the attitude of both the medical profession and the courts toward such cases is illogical and unscientific.

The question arises, what is a functional disorder? and why is not such a disorder in some cases as much entitled to consideration as the more imposing "organic" affections? Will anyone in the present era of cytology presume to claim that a so-called functional nervous disorder is without a basis of minute organic changes in the neurons? Why not abandon the misleading phraseology which assumes a paradox, *i. e.*, that a function can be disturbed without a change in its

organic basis; and boldly state, as a sound pathologic doctrine, that a neurosis is an organic fact. We have long thought that the more permanent stigmata of the grand neuroses should be grouped under some such designation as "organic hysteria." This is logical and consistent with what we have a right to believe occurs in the neurons in all the grave traumatic neuroses. A muscle that is paralyzed for many weeks, or contracted, or the seat of tremor, is a disabled muscle; and all it needs to dignify it in the sight of men and courts is an acknowledgment of the fact that its disability is not dependent on a caprice, or whim, or volition of the patient, but on some minute change in the cytoplasm of nerve-cells that is as real, though perhaps not as permanent, as the changes wrought by a poison or a process of degeneration. Surely pathology, of all the sciences, should no longer acknowledge the trammels of mere scholastic distinctions.

The Coroner as a Diagnostician.—The coroner of the city of Philadelphia is not an ordinary politician. What he knows about medicine is probably not in the books. Only the other day he undertook to decide that in the case of a child, who had been bitten by a dog, death was due not to hydrophobia, as the attending physician thought, but to the effects of the heat, and an automatic jury brought in a verdict accordingly. The municipal government of Philadelphia is well known to be unique, and although the coroner is a county officer, city and county are conterminous.

The Executive Committee of the Board of Trustees of the Philadelphia Medical Publishing Company adopted at its last meeting the following resolution on the death of Dr. J. H. W. CHESTNUT, a member of the Board:

"In the death of Dr. J. H. W. Chestnut the Board of Trustees of the Philadelphia Medical Publishing Company has lost a faithful member, whose wisdom and good judgment were a source of strength, and whose high professional character contributed largely to the esteem in which THE PHILADELPHIA MEDICAL JOURNAL is held by the medical profession."

Surgical Use of Suprarenal Extract.—J. W. Murphy (*Lancet-Clinic*, April 7, 1900) says he has employed suprarenal extract in more than 100 cases, covering most of the minor surgical operations about the eye, ear, nose, and throat. The field of operation is first sprayed with a 2% solution of cocain, then mopped with a 10% solution of suprarenal extract, then packed for 10 minutes with pledgets of cotton saturated with a 5% solution of cocain, and one pledget saturated with a suprarenal extract solution. When removed, the tissues are blanched and anesthetized. A painless and bloodless operation can then be performed, the anesthetic effect of the cocain lasting longer than without the suprarenal extract. In cases of hay fever, Murphy has employed a solution of suprarenal extract, by means of an atomizer, to the engorged mucous membrane with success. He has also employed a 2% solution of cocain, together with a 2% solution of suprarenal extract, after the Schleich method of infiltration-anesthesia, for the removal of sebaceous cysts, etc., and found that it rendered the operation both painless and bloodless. [M.B.T.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Smallpox at Erie.—At Erie, Pa., 7 cases of smallpox are reported and many persons have been exposed. The disease was brought from Cleveland, O.

Typhoid Fever in McKeesport.—During the first 9 days of August, 17 cases of typhoid fever were reported in McKeesport, Pa. The water-supply is thought to be at fault, and a special appropriation has been passed by the city councils for the cleaning of the water reservoir.

Polluted Water Causes Illness.—Diphtheria is prevalent in a suburb of Altoona, Pa., and 13 of the employees in the Pennsylvania Railroad shops, in the same city, recently became ill with nausea and cramps, and had to be taken home. Impure drinking water is supposed to be the cause.

Bathing in Reservoir.—Italians have been using the reservoir of the new Water Company at Chester, Pa., as a swimming pool. When it is considered that the water from the reservoir is used for drinking purposes by residents of the city and some adjacent towns, the enormity of the offence is apparent. The bathing has been done at night, and until recently was not discovered.

Formaldehyd in Milk.—Under the name of "Preservative," "Freezine," "Conerine" and "Milk Sweet" solutions of formaldehyd are being sold to milkmen in many parts of the United States. Chief Byrne, of Philadelphia, during the month of July secured 18 samples of formaldehyd adulteration and the parties will be dealt with according to law. The Act of 1895 reads as follows: "That the sale, or offering for sale, of milk for human consumption in this Commonwealth to which has been added boracic acid salt, boracic acid, salicylic acid, salicylate of soda, or any other acid, drug, compound or substance, shall be a misdemeanor and punishable by fine of not more than \$100 or an imprisonment not exceeding three months, or both or either, at the discretion of the Court."

Vital Statistics of Philadelphia for the week ended August 18, 1900:

Total mortality	550
Disease	Cases. Deaths.
Inflammation of appendix 2, bladder 4, brain 12, bronchi 4, kidneys 18, heart 4, liver 1, lungs 16, peritoneum 8, pleura 1, stomach and bowels 24, uterus 1, tonsils 1	96
Inanition 24, marasmus 27, debility 6	57
Sunstroke	56
Tuberculosis of lungs	54
Cholera infantum 42, morbus 2	44
Heart—disease of 36, neuralgia of 1	37
Bright's disease 13, uremia 13, diabetes 3 . .	29
Convulsions 19, puerperal 1	20
Apoplexy 10, paralysis 7	17
Brain—abscess of 1, congestion of 2, disease of 6, dropsy of 1, softening of 4	14
Casualties	13
Carcinoma of—breast 1, mouth 1, pharynx 1, stomach 4, tongue 1, uterus 2, sarcoma of lungs 1, tumor of brain 1	12
Drowned	13
Diarrhea 5, dysentery 5	10
Diphtheria	64 10
Old age	8
Typhoid fever	77 8
Cirrhosis of liver	5
Septicemia	4
Cyanosis	3
Burns and scalds	3
Epilepsy	3
Malarial fever	3
Teething	3
Arterial sclerosis	3
Scarlet fever	22 1
Abortion 1, alcoholism 2, asthma 1, atheroma 1, dropsy 2, erysipelas 2, senile gangrene 1, hemorrhage from stomach 1, from uterus 1, jaundice 1, measles 2, intussusception of bowels 2, obstruction of bowels 1, opium poisoning 1, surgical shock 1, suicide by shooting 2, syphilis 1, tabes mesenterica 1, tetanus 1, whooping-cough 2.	

The Contagious Diseases Hospital in Pittsburg.—Much opposition is being manifested by those residing in the vicinity of the municipal hospital of Pittsburg to the plan of the city director of public health, who proposes to locate the hospital for contagious diseases on land adjoining that occupied by the municipal hospital. *The Pittsburg Dispatch*, in an intelligent and well-considered editorial, points out the groundlessness of the alarm felt by those who object to having the hospital located in proximity to their homes. —[*New York Medical Journal*.]

NEW YORK.

The New York Health Board recently issued a peremptory order compelling the Street-Cleaning Department to cease using the dump at the foot of East Forty-third Street for garbage.

Poisoned by Passaic River Water.—Two women are said to have been poisoned by washing their hands in the Passaic River. The water is very foul and for years has not been used by the people of Newark, N. J., for drinking.

Claims for Tuberculous Cattle.—Claims against the city of New York for the destruction of cattle affected with tuberculosis or other disease have been audited to the amount of \$1,369 50 by the Health Board, the claims covering four years, 1896–1899. In all 61 cows were destroyed at an average cost of \$21.45 each.

Diphtheria Patient on Train.—Charles Radigar, suffering from diphtheria, came to Middleton, N. Y., recently from Livingston Manor on a crowded passenger train. He was quarantined as soon as his condition became known, but the authorities are apprehensive of serious consequences from the spread of the disease.

A Novel Suit Against the State.—A claim for \$30,000 has been filed against the State of New York by a militiaman of Poughkeepsie for the loss of a foot in consequence of injuries received while participating in a sham battle when he was on duty at the State Camp of Military Instruction at Peekskill, in 1899. He fell into a hole and the injuries were so severe as to call for amputation.

College of Medicine, Syracuse University.—The first class to complete the now required regular 4 years' course in the College of Medicine, Syracuse University, was graduated in June of this year. Of those who remained in the class at the beginning of the last session all were graduated. Recent reports from the Regents of the State of New York show that all who were graduated by the College passed the State examination. Of the graduates 22% have secured by competitive examination positions as internes in hospitals situated in New York, Boston, Providence, Detroit and Syracuse. Syracuse University should be congratulated. Its medical department with the motto "Standard of requirement high" is doing good and praiseworthy work in the interest of better medical education.

NEW ENGLAND.

A "new disease" is reported at New Bedford, Mass., which resembles smallpox and chickenpox, but is said by experts to be neither. It is highly contagious, although none of the patients has been dangerously ill and those first attacked have completely recovered. The patients will be quarantined.

No Brandy Drops for Children.—A crusade has been started in North Adams by the Massachusetts State Board of Health against the sale of brandy drops to children under 15 years of age. The candy secured contained over 1% of alcohol. The 5 dealers pleaded guilty and the cases were placed on file on payment of costs. Joseph Rudnick was fined \$10 for selling adulterated coffee.

Boston's Fountains.—Boston will keep its 30 iced-water fountains in operation for 50 days, a municipal appropriation of \$3,000 having been made for the purpose. Each fountain requires 600 pounds of ice a day. The water commissioner is about to experiment with a quadruple system of pipes reaching 100 feet under ground, which will

give the water a circulation of 400 feet before it is drawn at the faucet, at a temperature, it is expected, of 50 degrees, and that it is cool enough without the use of ice.

Infants Poisoned by Milk.—Dr. Lindsley, secretary of the Connecticut State Board of Health, in his monthly report says that most of the 400 babies that died in Connecticut in July were victims of poisoned milk or other unsuitable food. He says: The hasty inference that heat has been the chief or only cause of disease and death among infants is a fallacy. It is true there is some proportional relation between excessive high temperature and infantile mortality, but the parallel between high temperature and high mortality of infants, among different surroundings and conditions, in the same community, is too often wanting to prove that heat alone, unaided by other influences, is the sole and direct cause.

CHICAGO AND WESTERN STATES.

St. Anthony's Hospital.—The Sisters of St. Francis are building a \$20,000 addition to St. Anthony's Hospital, Denver.

Smallpox in Washington.—Near Goldendale, Wash., 18 cases of smallpox are reported and 25 cases are reported in Skamania County.

New Hospital at Red Bud.—The St. Clement Hospital at Red Bud, Ill., is now completed and ready for the reception of patients.

Milk Dealers Arrested.—Of the 13 milk dealers in Flint, Mich., 9 are in trouble with the State for using chemical preservatives in milk.

Rush Medical College.—It is reported that Dr. Edwin Klebs has resigned the professorship of pathology in Rush Medical College, Chicago.

Berkeley Hospital Corps.—Several hundred ladies of Berkeley, Cal., have joined the Berkeley Hospital Association as an auxiliary committee.

Physician for Governor.—Dr. Gilbert Shepherd, of La Crosse, Wis., is named as one of the possible candidates for the governorship on the Prohibition ticket.

Horses With Glanders.—Horses and mules in South Chicago are said to be affected by glanders. One horse has been killed and several others are said to be afflicted.

New Hospital for St. Louis.—A bill appropriating \$258,000 from the special fund for the erection of a new City Hospital in St. Louis was passed unanimously in the House of Delegates, signed by the Mayor, and in 10 days will become a law.

Medical Defence.—A movement has been set on foot by the members of the Ramsay County Medical Society, Minn., to establish a defence union on the English model. A committee was appointed to investigate the system, and report the result of the inquiry at the next meeting of the State Medical Society.

Increase of Typhoid.—There have been 282 cases of typhoid fever, with 54 deaths in St. Louis since March 1 of this year, against 119 cases and 27 deaths for the same period last year. Some physicians attribute the condition to disease germs in the water, due to the influx into the Mississippi River of Chicago sewage.

Swindled Country Stores.—William Schmidt, of Nashville, Ill., has a novel swindling scheme. His plan was to call upon the proprietors of country stores, ask if they sold patent medicines, and then demand to see their permit from the board of pharmacy, the law providing that all such stores secure a license to sell patent medicines. Schmidt represented that he was an agent of the board of pharmacy, and threatened to arrest the storekeepers unless they paid him a fee of \$10. He represented that it was cheaper to pay him than to be arrested and taken to Springfield for trial. Requests for permits have been coming to the board of pharmacy in great quantities from the sections visited by Schmidt.

Cigarets Forbidden.—The Rock Island Railroad Company has followed the example of the Union Pacific by placing a ban on cigarettes. Notice has been served on the employees of the company in the Armourdale, Kas., yards that those who are addicted to the use of cigarettes must give them up or lose their positions.

A memorial tablet was dedicated at Mackinac Island, July 10, to Dr. William Beaumont. The inscription on the stone reads: "Near this spot Dr. William Beaumont, U. S. A., made these experiments upon Alexis St. Martin which brought fame to himself and honor to American medicine. Erected by the Medical Society of the Upper Peninsula of Michigan, July 10, 1900."

Construction of School Houses Regulated.—The State Board of Health of Indiana recently sent out instructions to secretaries of county boards of health calling their attention to an order regulating the construction of schoolhouses. The floor must be three feet above the ground, and there must be solid foundations. The rules refer particularly to one-room schoolhouses.

Sues Insurance Company.—Dr. Robert Kitto, of Racine, Wis., has begun suit to recover \$1,000 from the Frankfort Insurance Company of Germany. By accident a piece of glass entered his eye and the member was so badly injured that it had to be removed. He carried accident insurances of \$50,000. On account of the accident he was entitled to \$17,000 of this amount.

Tuberculous Foreigner Denied Landing.—Secretary Gage of the Treasury, and Commissioner Powderly of the Immigration Bureau, have decided that tuberculosis of the lungs is a contagious disease and that aliens afflicted with it shall not be allowed to land in the United States. The decision was made in the case of the Rev. Tanijoio Kasbahara, who arrived at San Francisco on the *America Maru* in the latter part of July.

Scramble for Bodies.—A recent death in the county hospital at Chicago revealed the fact that considerable competition had been going on among neighboring undertakers for the possession of bodies. When a death occurs the employees of the hospital inform the undertakers, who telegraph at once to the relatives and use the reply in obtaining the body. It is said that in some cases the friends receive as many as a dozen telegrams asking what shall be done with the body.

Smallpox Among Indians.—Smallpox has broken out among the Turtle Mountain Indians in North Dakota. There are 24 cases in the hospital and others quarantined at home. Commissioner of Indian Affairs Jones has wired the agency authorities to take all steps necessary, including the employment of a trained nurse. The department also has shipped vaccine virus to the reservation. About 1,000 or 1,200 Indians are on the Turtle Mountain Reservation, which is close to the Canada boundary line and often visited by the Canadian Creek Indians.

Christian Scientists Convicted.—Some months ago 2 lady Christian Scientists of Milwaukee, Wis., were indicted for practising medicine without a diploma. A fatal case of diphtheria offered grounds for the complaint. The defendants were convicted and fined. We believe this is the first case against Christian Scientists successfully fought in the courts. More recently F. X. Schaffer, a graduate for the defunct Independent Medical College of Chicago, was also convicted by the same tribunal of being improperly qualified to practise medicine. This case was made interesting by the defendant's introducing as evidence of previous preparation in the study of medicine certain letters purporting to be from and signed by the dean (Zumm) of the University of Prague, and testifying to his having studied there. It was proved that these letters were forgeries, and that the Prague University letter-heads, as well as the University seal, were made in Milwaukee.

SOUTHERN STATES.

A Pasteur Institute and Laboratory has been established in Atlanta with the approval of the Medical Association of Georgia.

The Delaware Hospital fund has reached \$19,000, and the buildings will soon be begun at Wilmington.

Appointed Surgeon.—Dr. Charles C. Marburg has been appointed a member of the police and fire surgeons of the District of Columbia, in place of Dr. J. Ramsey Nevitt promoted to coroner.

Officials Bathe in Reservoir.—Alderman Allen, Policeman Cunningham, and others of the party recently indicted for bathing in the reservoir at Charlotte, N. C., whence the water-supply of the city is drawn, were bound over under a heavy bond to appear at the next term of the Criminal Court on the charge of defiling the city's drinking water.

Fumigated Vessels for Chagres Fever.—Officials thoroughly disinfected the Norwegian bark *Kotka*, which is at Cape Charles quarantine, having been towed in with 6 cases of chagres fever aboard. The *Kotka* left Brunswick, Ga., August 3, for Liverpool, and the fever developed after leaving Brunswick. The bark is reported to have been at South American ports.

A Menace to Health.—Dr. John S. Fulton, of the Maryland State Board of Health, is making efforts to put an end to the hauling of night soil from Baltimore and distributing it over the surrounding country. Although it is a violation of the law, it has become so general as to threaten to pollute the streams from which the water-supply of Highlandtown and Canton is taken. The law provides that it be drawn to the city scows.

New Orleans Death-Rate.—Only 83 deaths were reported in New Orleans last week. This is said to be the lowest figure known there. The total includes 5 deaths from accident or suicide, leaving the mortality from disease only 11.96 per 1,000, which would give an average duration of life of 34 years. The summer is the healthiest season in New Orleans, its death-rate falling to half what it is during the worst part of the winter. Cholera infantum, the scourge of some Northern cities, claimed only 2 deaths for the whole week.

Abating Smoke Nuisance.—To comply with the smoke law is no easy matter. It prohibits the emission of "dense black or gray smoke" without regard to the duration of the same. No smoke-consuming device has yet been made which will prevent the issuance of smoke during the time the furnace door is open and for a few seconds after it has been closed. The health-officer of the District of Columbia has been making inquiry as to this nuisance. Hard coal has been tried and many devices which have proven ineffective have been abandoned.

Kentucky Whisky.—The statistical report of the whisky made in Kentucky for the fiscal year ended June 30 has just been issued and shows the production to have been 21,789,722 gallons, against 19,788,788 gallons of the previous year. During last season the smallest amount of whisky made in any one month was made in September, 1899, when the production only reached 50,699 gallons. The largest amount made during the year was made in April, the production being 3,837,232. The statistics further show that 20,219,739 gallons were withdrawn during the fiscal year just ended, as against 17,997,698 for the last fiscal year. On June 30 there was in bond in Kentucky 82,604,906 gallons of whisky and during the month of June 50,252 gallons were exported from the State.

CANADA.

Typhoid in Winnipeg.—An epidemic of typhoid fever threatens Winnipeg. There are nearly 100 cases at present and others reported daily. The disease is also raging in many parts of the province, and every day cases are brought to Winnipeg general hospital.

MISCELLANY.

Hospital Corps in China.—There are in China on en route to that country 8 hospital stewards, 21 acting hospital stewards and 298 privates, and with the Fourteenth U. S. Infantry, grade not known, 21, in all 348.

No Lodge-Doctors for Victoria.—Victoria, B. C., physicians have passed a resolution, refusing to act as "lodge-doctors."

Plague in South America.—Several new cases of plague are reported in Rio Janeiro, while the government of Paraguay has announced that plague has disappeared from the Republic.

The "Solace" Sails.—The *Solace* bringing home the sick and wounded from China, sailed August 13 from Yokohama for Guam, which will be her first stopping place on her homeward trip.

Economy.—A scheme is on foot to convert the mud at the bottom of the Thames river into fuel. This affords a new encouragement with reference to drinking water at certain seasons. Perhaps the thrifty householder can save it up and burn it.

Death-Rate.—Many cities in the United States do not calculate the death-rate on the same basis. Minneapolis and some other cities do not include stillbirths, premature births, or deaths by violence, while Boston and New Orleans count everything except stillbirths.

Bubonic Plague Serum.—Haffkine serum is said to have a bad effect upon the faculties for a few hours after inoculation, and there is considerable pain, but the stupor soon passes off and in 8 or 9 hours there is nothing to remind one that he has taken the newly discovered plague-preventive.

Sickness in Alaska.—The Treasury Department has received the following telegram from Lieutenant Jarvis, of the Revenue Cutter Service: Report current in States of sickness at Nome unfounded. No typhoid fever, 12 cases of measles, 18 cases pneumonia, and 6 cases smallpox in isolation. All convalescent.

Health of Troops in Philippines.—General MacArthur has cabled the War Department a brief statement concerning the health of the troops in the Philippines. The number of sick in the hospitals is 3,868, and in quarters, 1,261; making a total of 5,129 sick soldiers; or 8.47% of the entire army in the archipelago.

For Service in China.—Either America is a very healthful country or else the crop of young surgeons contains a large amount of highly developed patriotism. Several weeks ago the Surgeon-General of the army called for 100 contract surgeons for service in China. Up to the present time over 1000 applications have been received, of which the first 100 have been appointed.

Remarkable Mortality at Ponce.—The Marine-Hospital Service official at Ponce, Cuba, in a report just received says that in Ponce City and surrounding country for the 2 weeks ended July 28 the enormous death-rate has slightly increased. There were 216 deaths, against 70 births during this same period. An investigation into the remarkable mortality is being conducted by the Superior Board of Health.

Hospital Corps for China.—Hospital Steward Richard H. McComyn, at Fort Porter, N. Y., has been ordered to conduct a detachment of hospital corps privates from Jefferson barracks, Missouri, to Fort McDowell, California, to accompany Maj. John V. R. Hoff, surgeon, on his journey to China. Major Hoff will be the chief surgeon of the staff of General Chaffee and will have charge of the establishment of field hospitals for the army.

Obituary.—J. H. W. CHESTNUT, of Philadelphia, at Alaska, August 5, aged 45.—THOMAS J. THORPE, of St. Louis, August 12.—J. W. BLACK, of Kennett, Mo., August 13.—THEODORE C. LAVERTY, of Middletown, Pa., August 14, aged 69.—EDWIN EVANS, of Rome, N. Y., August 16, aged 56.—SOLOMON A. VON GUMP, of Vienna, Mo., August 15, aged 42.—E. W. OLIVER, SR., of Mulberry Grove, Ill., August 15.—CARL M. KELLEY, of Matamoras, Pa., August 11, aged 38.—SAMUEL H. GISH, Janesville, Wis., August 2, aged 79.—LAWRENCE E. ELROD, of Longmont, Colo., August 17.—FRANKLIN BOOTH, of Elmhurst, N. Y., August 19.—CHARLES W. PARSONS, of Louisville, Ky., August 18.

Bubonic Plague Bacilli.—W. H. Hill, bacteriologist to the Board of Health of Boston, completed an examination of 2 cultures received from Johns Hopkins University, sent from the University of California, and which were taken from a Chinaman supposed to have bubonic plague. Dr. Hill developed the cultures and inoculated a white rat. The rat died in 3 days. Afterward the bacilli were taken from the tissue, and the results obtained were typical of bubonic plague. Dr. Hill has forwarded to the University of California his opinion that the bacilli are those of bubonic plague.

Sick Soldiers from Manila.—News has been received that the transport *Thomas* will bring 216 sick and 4 insane soldiers from the Philippines. Major Harvey, who has been for some time surgeon-in-chief at the post hospital, will soon leave to take the post of commanding officer of the general hospital now being established by the Government at Nagasaki, Japan. He will be succeeded at the post hospital by Colonel Benjamin F. Pope. The record of the plague in Manila for the 2 weeks ended July 7, as just reported to the Marine-Hospital Service, is 7 new cases, and 5 deaths. Of the new cases, 4 were Filipinos and 3 Chinese.

Lax Quarantine Laws.—After 10 days without a case of plague instead of 31, as was Honolulu's rule, the port of Sydney, Australia, was declared free from this disease, and though other cases arose afterward Sydney is still officially clean. It is stated at Sydney that international law allows the declaring of the port clean in such a case, as the disease is not "epidemic." According to this construction Honolulu suffered several months of needless quarantine, as the plague there was sporadic during most of the time while it was declared to exist. Quarantine in Honolulu was not raised till there had not been a case for 30 days.

Lepers in Philippines.—Surgeon-General Sternberg has received a report from the President of the Board of Health in Manila, stating that the Board of Health is considering a plan to segregate all the lepers on one island, where hospitals and other suitable buildings will be erected for their care. The report states that leprosy was introduced in the Philippines in 1633, when the Emperor of Japan sent 150 lepers to the islands. Since then the number has increased until the estimate is that there are 30,000 lepers in the archipelago, largely in the Visayas. In a recent inspection of Manila, 100 lepers were found concealed in various houses, while many others escaped to the country.

Quarantine Service in Philippines.—The Chief Quarantine Officer for the Philippine Islands reports on an inspection of Philippine ports of entry with reference to quarantine service. He recommends that a small station with barrack accommodations for 100 people be equipped at Iloilo; also recommends a small floating and disinfecting plant and limited barrack accommodations at Cebu. Assistant Surgeon L. D. Fricks has been detailed as Quarantine Officer at Iloilo and Assistant Surgeon H. A. Stansfield to take charge at Cebu. During the week ended June 23 only 2 cases of plague occurred in Manila, 1 Chinese and 1 Filipino, and neither had resulted in death.

Home for Soldiers at Manila.—Encouraged by the wife of Governor Stanley and other ladies of Kansas, a proposition has been made to establish at Manila a home for the soldiers of the United States, somewhat after the fashion of the Christian associations and similar efforts in this country to counteract degenerating influences, the home to be called the Clara Barton Home, and to be established under the sponsorship of the National Red Cross Society, though it is also proposed not to involve that society financially, but to obtain contributions for the support of the home from those States from which have been recruited volunteer regiments now in the Philippines.—[*Medical News.*]

Sanitary Conditions Improved.—United States Minister Merry at San Jose, Costa Rica, has submitted an interesting report upon sanitary conditions at the port of Limon, to the Department of State. He says that the sanitary conditions at the port of Limon have been much improved, doubtless on account of the \$8,000 expended there by the government of Costa Rica in public improvements. No tropical port with a banana-producing country in its contiguous interior can be entirely free from malaria, but the

fact that Limon has been, thus far during the present year, practically free of yellow fever is suggestive of encouraging results in combating that disease by sanitary improvements, and indicates that this may now claim to be one of the healthiest banana ports in Central America.

Large Order for Quinin.—Recently the U. S. Government has ordered an immense quantity of quinin to be made into pills and tablets and shipped to the Government stores, ready for requisitions from China or the Philippines. Hundreds of pounds of this drug are required to meet the demands made by sickness in the army. During the Civil War quinin cost the Government between \$2 and \$3 an ounce, and it became one of the most costly essentials for carrying on the war. Grown almost exclusively in Ecuador, Peru, and Bolivia, the cost of transporting the bark across the mountains from the interior of Ecuador, Peru, and Bolivia to the seaport towns was enormous. Since then cinchona has been obtained in large quantities from Java. The present price of quinin is about 37 cents an ounce, and it is obtainable in much larger quantities than during the Civil War.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended August 17, 1900:

SMALLPOX—UNITED STATES.			
		CASES.	DEATHS.
KANSAS:	Wichita Aug. 4-11	1	
LOUISIANA:	New Orleans Aug. 4-11	16	2
MINNESOTA:	Minneapolis July 14-Aug. 4	22

Increase of Disease.—The health reports of Honolulu for the months of June and July show an alarming increase in the death-rate, especially among native Hawaiians and Japanese of the island of Oahu. In June the number of deaths per thousand was 45, in July 49. The increase for the past few years, as shown by tables just compiled, has aroused

a good deal of discussion. In 1896 the July deaths numbered 48. Since then the figures have jumped to 59, 75, 93, and this year 114. Tuberculosis heads the list of diseases, and there is agitation for strict measures to quarantine patients. The Board of Health is discussing a quarantine against tuberculosis, as many people come here from other places to enjoy the mild climate, and it is believed that they are a source of danger to the population. Typhoid fever has also claimed a good many victims lately, a slight epidemic having developed in one district of Honolulu.

Yellow Fever in Havana.—August opened with 35 cases of yellow fever in Havana. There are 59 cases in the city at present, 4 of the victims being Americans. There were 30 deaths from the fever during July, and there have been 11 thus far in August. Yellow fever cases this year have been principally confined to the locality just west of Central Park, known as the new city. Scarcely any cases have appeared in what has heretofore been known as the "yellow belt," in the vicinity of the arsenal and the wharves. This is accounted for by some observers by the fact that a great amount of sanitary work was done in the old part of the city last year, and electrical disinfectants have been continually used there. Confidence is expressed by the authorities that there will be no general fever epidemic, as immunes are widely scattered. The condition is regarded as normal compared with other years, when immigration reached the present figures. The cases are largely confined to Spaniards and Canary Islanders, many of whom have come to Havana in the last 6 months. It is expected the cases will average one a day during August. This is usually the worst month for yellow fever. Men of the sanitary and street cleaning departments are actively at work in the infected district. All suspected cases are sent immediately to hospitals.

Foreign News and Notes.

GREAT BRITAIN.

Plague Case in the Thames.—The British steamer *Clan Mac Arthur*, which sailed from Calcutta via Port Said, for London, has been quarantined in the Thames owing to a death from bubonic plague having occurred on board the vessel.

An Asiatic Woman an M.D.—The first Eastern woman admitted to the licenses of the Royal College of Physicians and Surgeons, Ireland, received her diploma recently. It is said that she made a most brilliant examination for her final, having been the only candidate who passed with honors.

The Owens College.—The council has appointed F. A. Southam professor of clinical surgery in place of W. Whitehead, resigned, and G. A. Wright professor of systematic surgery in place of the late Prof. T. Jones. These appointments are subject to the confirmation of the Court of Governors which will meet in October.

Carbolic Acid, a Poison at Last.—The Privy Council have at last consented to place carbolic acid among the poisons included in Schedule A of the Pharmacy Act. In future, therefore, all liquid preparations of the acid and its homologs, containing more than 3% thereof, with the exception of duly-labeled preparations in closed vessels for agricultural and horticultural purposes, will have to be sold in accordance with the regulations governing the sale of poisons.

Asylum Reports.—The average number of patients during the year 1899 in Saint Andrew's Hospital for Mental Diseases, Northampton, was 377, comprising 186 males and 191 females. The admissions numbered 103, 35 males and 68 females. Of these 19 were readmissions. The number of admissions has continued to increase steadily for the year 1899, as compared with 86 for the previous year and 73 for the year 1897. During the year 36 patients were discharged as recovered—14 males and 22 females—a total of 9.5% of the average number resident. The deaths during the year amounted to 22—17 males and 5 females—a total of 5.8% as calculated on the same basis. The number of patients on the books of the West Sussex County Asylum, Chichester,

at the beginning of the year 1899 was 466. The average number resident during the year was 478 patients, 217 males and 261 females. During the year 100 cases were admitted—39 males and 61 females. Of these 5 were cases of readmission.

Typhoid Fever in Belfast.—The death-rate from typhoid fever in Belfast is 4.46 per 10,000, while in Manchester it is 1.17 and 2.16 in Birmingham. As to the causes reference has been made to the water-supply, sewerage, houses with bad privy and ashpit arrangements, presence of polluted old streams, and arrangements have been made to combat these causes. An examination of the water failed to show any recent increase in contamination and that showed the present outbreak must be due to other causes.

University of St. Andrew's.—The Marquis of Bute's offer of £20,000 for the establishment of a Chair of Anatomy in the University of St. Andrew's, though welcome enough to the recipients, has excited feelings of a very different order in the medical dovecot of Dundee, where the gift is regarded "as another evidence of the donor's inveterate hostility to the young medical school" there. It is urged that both schools cannot be a success, and evidently the Dundee people are apprehensive lest this £20,000 should prove the means of their undoing in matters educational.—*Medical Press.*

The Royal Institute of Public Health.—The annual congress of the Royal Institute of Public Health was held recently at Aberdeen. Lord Aberdeen in his presidential address reviewed the progress of sanitation, especially as represented by legislation upon the subject. It is exactly 100 years since the first enactments were passed which could be described as the direct ancestry of modern sanitary legislation. The earlier Factory Acts, designed especially for the protection of the children might come under this category. Another kind of legislation which advanced concurrently took its origin in the necessity which had to be faced in crowded communities for an organized supply of water as distinguished from independent and casual pumps and wells. So, too, with sewerage. Prof. J. W. Simpson, of London, presided over the Preventive Medicine and Vital Statistics Section, and in his address said that such advance had been made in preventive medicine that the soldier who went to India today was 5 times less liable to die than his predecessor who was there when Queen Victoria began to reign. He strongly advocated the formation of a special sanitary service in connection with troops going on foreign service, pointing out that more deaths occurred from disease in a campaign of any magnitude than from wounds. In the section devoted to bacteriology and pathology, Professor Hamilton, of Aberdeen University, spoke of recent developments in bacteriology, dealing specially with the evil done owing to the failure to properly clean railway carriages, tramway cars, and other public vehicles. Dr. Farquharson, president of the Municipal and Parliamentary Hygiene Section, dealt with the good work being accomplished in public-health matters by parish councils, which should have more extended powers. The port sanitary authorities, presided over by Alderman Fraser, of Hull, resolved to urge the Local Government Board to supply as early as possible any information as to the existence of infectious or contagious diseases at the various foreign ports, and a deputation was appointed to wait upon the President of the Local Government Board and lay the matter before him. In the Preventive Medicine Section, Dr. Hope (Liverpool) opened a discussion on "Municipal Laboratories as Part of Public Health Organization," and resolutions on the subject were adopted. Dr. Dean, of the Jenner Institute, London, read a paper in the Bacteriology Section on "Toxins and Antitoxins." Dr. Browning (Weymouth) drew attention to the danger arising from sacramental cups at communion, many people taking wine from the same vessel, and he suggested that the clergy should be approached and asked to alter the present system. In the Municipal and Parliamentary Hygiene Section the Earl of Aberdeen read a paper by the Countess of Aberdeen on "Women as Members of Sanitary Authorities."

CONTINENTAL EUROPE.

German Universities.—The number of students at the German universities is larger by 5,000 than it was 10 years ago.

Smallpox and Flies.—A French physician, Dr. Her-
vieux, has made investigations which indicate that flies spread
smallpox.

The Congress of Spanish Surgeons, which was to
have been held in September of the present year, has
been postponed until 1901.

The Centigrade Thermometer will alone, in the
future, receive official recognition in Germany, and Réumur
thermometers will no longer be tested by the government
department.

New Hospital in Athens.—A hospital of 12 buildings,
4 of which are isolated for contagious diseases, has been
erected at Athens. It is for children and is called "Saint
Sophia" in honor of Princess Sophia of Greece.

A Medical Discovery.—The *Pall Mall Gazette* publishes
a dispatch from Rome, which declares that an important
medical discovery, the cause of Bright's disease, has been
made by Dr. Ovid Brown, formerly of New York, and now
of Rome.

Marseilles Medical Strike.—All the surgeons and stu-
dents at the Marseilles hospitals have gone on strike on ac-
count of the suspension of one of their colleagues and a dis-
pute with Dr. Isoard in regard to the management of the
hospitals.

The Blind in Russia.—It is stated in the *Medical News*
that there are more than twice as many blind persons in
Russia as in the whole of the rest of Europe. They number
190,000, which is equivalent to 2 in every 1,000 of the popu-
lation. In France and England the proportion is not quite 1
to 1,000.

To Protect Cattle Against Texas Fever.—A dis-
covery of much interest has been communicated to the
Academy of Medicine by M. Linnière, of Paris, one of the
leading scientists on veterinary subjects, who claims to be
able to preserve animals from Texas fever, the worst form of
parasitic maladies. M. Linnière has succeeded in cultivating
the parasite producing the disease in serum from animals
which have been previously attacked, thus attenuating its
virulence, and in obtaining a vaccine virus with which to
inoculate and protect cattle against the fever.

**Permission Given to Establish an American
Hospital in Japan.**—The Department of State has been
informed by Minister Buck, at Tokyo, that the Japanese
Government has given permission to the United States Gov-
ernment to establish a United States hospital on Japanese ter-
ritory wherever the United States Government may select a
site.

Paris Water from the Swiss Lakes.—The scarcity
of water in Paris during the drought has raised the question
of providing for an additional supply from the Swiss Lakes.
Lake Lemán, 250 miles from Paris, and Lake Neuchatel have
been spoken of. At the close of the Revolution the Parisians
got all their water from 63 public fountains, and it was only
40 years ago that an efficient service of water was distributed
in the capital.

Institution for the Study of Tropical Diseases.—
The first German institution for the study of naval and
tropical diseases will be opened at Hamburg, October 1, at
the cost of the Hamburg Senate and with the support of the
Colonial Department of the Foreign Office. It will be a
hospital for seamen and residents from the tropics suffering
from internal diseases, and for the study of naval hygiene
and the training of naval doctors.

Antirabic Inoculation in Greece.—The number of
patients who underwent the treatment for hydrophobia at
the Pasteur Institute of Athens from the foundation of the
institute in 1894 to the end of 1898 was, according to the
British Medical Journal, 1,300. Of these 1,200, or 92.8%, had
been bitten by rabid dogs, 58 by cats similarly afflicted, 7 by
asses and mules, 4 by pigs, 2 by cows, 2 by wolves, and 1 by a
horse. In 18 cases the disease was transmitted by human
saliva, and in 1 by the bite of a man suffering from hydro-
phobia.—[*Boston Medical and Surgical Journal*]

New Process of Embalming.—Dr. Variot, of Paris,
has discovered a process for embalming bodies which it is
thought will prove a great success. He not only embalms,
but metallizes the bodies by the Ruolt process, just as it is
done with a fork or a spoon. In this manner they can be
preserved indefinitely, and in such perfection that the most
im perceptible wrinkles and lines are reproduced, and the
embalmed body has the appearance of a metal statue.

To Revitalize Air.—Interesting demonstrations of the
properties of sodium dioxid were given recently before the
French Academy of Science. Sodium dioxid is found to pos-
sess the property of renewing the oxygen in air that has
been breathed and in absorbing carbonic acid gas given off.
Thus, with an apparatus containing the sodium, shown by
Desgrey and Balthouard at the Academy, a diver can remain
under water and walk about without having the air renewed
by the pumping apparatus at present employed. By means of
the new apparatus miners will be able to penetrate into poi-
sonous gases and foul air, and firemen into smoke, without
fear of asphyxia. It will also render practicable submarine
boats. Ample proofs of all that is claimed for it were given
at the Academy. Two men put on diving dress from which
all air was excluded and remained inclosed 2 hours.

**The Fourth International Dermatological Con-
gress**, under the presidency of Dr. Besnier, and most suc-
cessful in every way, has just ended. The next congress will
be held in Berlin with Prof. Lesser as its president. Dr. J.
Nevins Hyde, of Chicago, Dr. Henry W. Stelwagon, of Phil-
adelphia, and Dr. J. Caspar Gilchrist, of Baltimore, who were
present and read papers, extended to the members, in the
name of the American Dermatological Association, a cordial
invitation to hold the next meeting in the United States. It
seems, however, that Berlin had a claim for the Congress
this year (1900). Paris having already had one previously;
but at the last Congress, held in London, the French rep-
resentative requested as a special favor, owing to this being
exposition year, that it be held there. This was conceded,
with the distinct understanding that Berlin should have the
next. The American representatives above, learning these
facts, graciously stood aside, and gave their support to Berlin.
In return for this courtesy the moral word of the Congress
was voluntarily given that the Congress following that of
Berlin would be held in New York.

MISCELLANY.

Rains in India.—The following dispatch has been re-
ceived from the Viceroy of India: "The favorable conditions
continue. Rain is falling generally throughout the country.
The total number supported in all the famine-stricken prov-
inces is still large, owing to the backwardness of the crops,
the restricted demands for labor in the fields, and high prices.
About 6,149,000 persons are receiving relief."

Obituary.—PROF. A. BORN, of Breslau, aged 50.—DR.
MOUSSIER, surgeon to the Nantes hospitals.—DR. SUTUGUIN,
of St. Petersburg Medical Academy.—HERMANN DONNERO,
of St. Petersburg, has been assassinated.—DR. KRISTELLER, of
Berlin.—ROBERT JOHN SPITTA, of London, August 2, aged 81.
—WILLIAM JOHNSTON STUART, of London, August 3, aged 81.—
HENRY BURFORD NORMAN, at Chesham, Bucks, July 26,
aged 81.—WILLIAM CHARLEY, of Shrewsbury, August 2,
aged 55.—SIR WILLIAM STOKES, of Durban, August 19,
aged 61.

The Society of Red Cross Dogs, founded in 1893, is
under the patronage of crowned heads and army surgeons.
There are about 300 members enrolled, and the entire sys-
tem of training and supplying these animals is undertaken
gratuitously by the society, the annual subscription amount-
ing to a trifle under a dollar. The kennels and training
establishment are situated in a small Rhenish Prussian
town, Lecheich, where about 20 dogs are kept at a time.
When 5 months old the training begins, and continues until
the animal is absolutely under control, from scouting in the
open field and taking messages to the more difficult task of
searching for the wounded and attending to their needs in
the thickly girt forest.

Society Report.

THIRTEENTH INTERNATIONAL MEDICAL CONGRESS, Paris, August 2-9, 1900.

It has taken less than two years to complete the preparation and organization of this international rendezvous, and that it has proved a success is evidenced by the fact that some 6,000 have been in attendance, of whom nearly two-thirds were from countries outside of France. The streets adjoining the Ecole de Médecine lost their wonted appearance at this time of the year of peaceful tranquility; numbers of practitioners from all parts of the world hurried along, anxious to take part in the scientific labors of the sectional meetings and in the varied and magnificent fêtes, which, given in what is *par excellence* the City of Fêtes, caused visitors to bear away an ineffaceable memory of the realization of a delightful dream. Of all the International Congresses which have taken place, or will take place during the Exposition, the Medical Congress was certainly the most distinguished and the most interesting. It will also prove to be undoubtedly the most important of all medical medical meetings which have been held up to now. The most renowned *savants* have willingly devoted a portion of their time to the Congress: Drs. Osler and Keen in America, Sir William MacCormac in England, Virchow at Berlin, Professor Pachontine at St. Petersburg, Golgi in Italy, Zambacho Pascha in Turkey, and many others have been its initiators. In France the indefatigable Dr. Chauffard, the general secretary of the Executive Committee, has given himself up entirely to it.

The arrangements of the Congress were made by the Government Department, with the following executive committee: President, M. Lannelongue; secretary-general, M. Chaffard; treasurer, M. Duflocq; members, MM. Bouchard, Bonil'y, Brouardel, Dieu, Gariel, LeDentu, Malassez, Nocard, Raymond, Rendu, Roux; secretaries, MM. de Massary and Leon Weber. The president of the Congress, M. Ochilon Marc Lannelongue, is professor of surgical pathology in the faculty of medicine of Paris, and surgeon to the Hôpital des Enfants Malades, and was enrolled an honorary fellow of the Royal College of Surgeons of England at the recent centenary.

It had been feared that the assassination of King Humbert would mean the abandonment of the official receptions and this proved true in a great measure, sadly clouding over the more cheerful side of the gathering.

One of the most noteworthy of the smaller gatherings was the banquet tendered Lord Lister by Prof. Richet and the Scientia Society, at which addresses lauding the achievements of the guest were made by all the leading French scientists. The reply by Lord Lister was particularly happy. He said he had accepted the invitation to the banquet because he interpreted it as an expression of the respect of French scientists for the noble science of surgery and for the Royal Society of which he was president. He also thought that such a fête given by such eminent Frenchmen to an English scientist was a striking illustration of the happy fact that though there were misunderstandings, science knew nothing of them. Scientists had learned to respect each other—better still, to love each other—whatever might be their nationality. He had often stated, and he was pleased to repeat it, how much he was indebted to Pasteur. He had ever loved physiology and surgery, but he had lamented the disastrous results that followed even the best and most skillful operations. He saw that the chief evil was due to changes that occurred after the operation, and to a cause arising not from within but from without the patient's body. He did what he could to guard against this, but all efforts were useless till Pasteur threw a powerful light on the subject. Pasteur had suggested a possible course which he, the speaker, had done his best to follow. That was all. If the results had been so beneficent as generously described by the various speakers that night it had been to a great measure due to accident.

The opening general meeting of the Congress took place, Thursday, August 2, with the official ceremony in the vast Salle des Fêtes in the Exhibition. Owing to the assassination of the King of Italy, the President of the French Repub-

lic was not present, but he was represented by the Minister of Justice.

President Lannelongue read the opening address, welcoming the members of the Congress. In terminating, he said: In wishing you welcome, I offer you my warmest congratulations. I most heartily thank the committees of all the foreign countries who have helped in the organization of this vast undertaking; the entire press for its active and disinterested aid; the Executive Committee, who have never failed to respond to my call, and have given the best of their advice; the University of Paris and the members of the Government of the Republic, who have understood from the first the importance of our task, and have rendered its realization easier. As to myself, my heart is filled with the keenest emotions I have ever felt in my life. I can find, in conclusion, no better words than those addressed to you by Bouillaud, the first and one of the most illustrious presidents of this Congress: "Thanks to you, my whole life has just received its crowning award. I hold you in the depth of my heart, and you will continue to live there till its last beat." I will only add: Now to work, time is pressing; never since the beginning has there been promise of a richer or more plentiful harvest. May we know how to profit by it, and gather in the fruitful grain, which future generations will cause to bear more fruit.

The Minister of Justice, in the name of the Government, then welcomed the members of the Congress. M. Chauffard, the General Secretary, now read his report, describing the complex work of organization. As a result, 190 delegates, representing the governments of 34 foreign States, were present on the platform; 250 universities, academies, or learned societies have sent delegates, and over 6,000 members of the Congress have come to Paris. The program of the Congress includes 260 reports, and more than 1,200 communications.

After the termination of the Secretary's report, the official delegates of the foreign nations came forward to offer their good wishes to France, and hopes for the success of the Congress. Professor von Bergmann led the lengthy procession. Sir William MacCormac, Bart., K.C.V.O., represented Great Britain. Professor Baccelli was absent owing to the mourning of the Italian nation. M. Mandizabal, the delegate of Mexico, made a long spirited speech, which was greatly applauded. The delegate of Venezuela closed the series.

This terminated the official portion of the program, and a very small crowd gathered round the foot of the platform when PROFESSOR VIRCHOW rose to give his address on **Traumatism and infection**. The venerated professor, who was in the best of health and spirits, spoke in German. After a historical review of the subject, Professor Virchow expressed the opinion that the present attention to bacteria has withdrawn us too much from other causes of pathological processes. Injuries of bones take place without abrasion of the skin, yet osteomyelitis ensues. Brain abscess results from head trauma. Some surgeons claim that microbes enter even through the slight lacerations of skin. This, however, is mere theory. We know that cells may degenerate without any microbial influence. Trauma may kill them. We know from dead parasites, such as trichina within the body, what happens to dead cells. The changes occurring in extrauterine fetuses also make this clear. Let us, then, not attribute too much importance to microbes, but let us study carefully the cellular changes as they occur. With the address of Professor Virchow, which was received with great applause, the proceedings terminated, the discourse of Professor Pavlov, which was included in the original program of proceedings, being postponed to the first general meeting.

The work in the 26 sections began generally at 9 A. M. on Friday morning, with the exception, however, of the sections of neurology and dermatology with syphilography. These sections are perhaps the largest attended. The section of neurology is at the same time the second International Neurological Congress, and is a question which will be decided before the end of the present Congress whether the International Neurological Congress as such shall cease to exist, or whether it will arrange its meetings at a different time to the International Medical Congresses. These two sections, owing to the great number of communications promised and the number of subjects for discussion, met on

Thursday morning at 9 A.M. and held morning and afternoon sittings every day.

RECEPTIONS AND SOIRÉES.

The President of the Congress and Madame Lannelongue gave a reception by invitation to the delegates and Presidents of Sections on Friday evening, August 3. The program included minuets and ballets by dancers from the Opera, while a Hungarian band played at intervals in the refreshment room.

The Committee of Organization gave a *soirée* in the Palace of the Senate and in the Luxembourg Gardens on Monday, August 6, at 9 P.M. The program included dancing and an entertainment in the Salle des Fêtes of the Palace. M. Mounet-Sully, of the Comédie Française, and Madame Sarah Bernhardt recited poetry, while the musical talent was supplied by M. Renaud and Madame Litvinne of the Opera, and M. Fugère of the Opéra Comique. As all the members of the Congress with their wives and families had been invited, the number of guest must have exceeded 15,000. Owing presumably to faulty organization the enjoyment of some hundreds was spoilt, as the sole entrance into the Palace, a door five feet wide, also served as the popular means of exit, so many guests never succeeded in reaching the door of entrance even, but after a struggle of half an hour or so gave up the attempt and left.

Dinners and *soirées* were given by the Presidents of all the Sections, and these smaller *fêtes* were a very enjoyable feature of the meeting to the fortunate guests.

Up to August 5, 6,170 members had registered their names, the nationalities being represented as follows: France, 2,293; Russia, 805; Germany, 572; the United States, 412; Italy, 324; Great Britain, 222; Spain, 219; Belgium, 147; Austria, 141; Argentine Republic, 108; Swiss, 101.

Owing to the initiative and energy of Dr. Blondel and the French Medical Press Association, a reception room and a work room have been placed at the disposal of the French and foreign press reporters. Here members of the press find the daily program and printed summaries of all the communications made in the various sections, and are able to write their articles and post them on the premises. Members of the French Press Association in rotation are always in attendance to give information and advice. It is interesting to note that this is the first occasion at an International Medical Congress when such facilities have been given to medical journalists and correspondents.

A general assembly of the Congress was held August 6 in the new hall of the Sorbonne. The paper of Prof. Pavlov, who was absent through illness, was read, dealing with experimental therapy and conveying a special tribute to Claude Bernard. SIR J. BURDON SANDERSON then read a paper on **Some modern pathological problems.**

PROFESSOR JACCHI from the United States followed and gave a very interesting account of the growth of the medical profession in America, of its medical education from its crudest beginning to the present day, and of the American medical press. This was all quite new to the greater part of the audience and was consequently welcome and entertaining. These three papers were lengthy and sufficed to fill up the afternoon.

Medicine.

Dr. P. LE GENDRE (of the Hôpital Tenon, Paris), read a paper on **Pathogenesis of gout.** All theories of gout were open to chemical, physiological, or pathological objections; the most plausible of them could only account for a fit of the gout and could not explain the permanent derangement of the cellular nutrition which was transmissible by heredity and formed the connecting link between successive gouty attacks in the individual and also between gouty manifestations in father and son. Clinical statistics had proved (1) that gout occurred with exceptional frequency in persons whose progenitors or descendants suffered from diseases of the class known as arthritic or from diabetes or obesity, and (2) that gout was often associated in the same individual with one or other of these maladies. If gout was clinically of the same nature as diabetes it was very probable that in the gouty there was an impairment of metabolism as regards nitrogenous matter, an inability of the tissues to effect the complete destruction of albumin. Among the consequences of the incomplete destruction of waste products

must be reckoned the loading of the organism (*a*) with certain acids (oxalic, acetic, lactic, etc.) which might diminish the solubility of uric acid, although it might not be necessarily in excess in the blood, and (*b*) with certain organic bodies the toxic action of which might contribute to produce the phenomena of gout. Clinical statistics showed that simple albuminuria and interstitial nephritis were frequent in gouty subjects. Acquired gout was brought on by excess in food which was either nitrogenous or rich in oxalic acid, or by overfree use of certain fermented beverages; it might also be due to want of bodily exercise, to overfatigue of the nervous system, or to leadpoisoning. Gout was hereditary because the defects of the cells of the progenitor were continued to those of the offspring through the ovule or the spermatozoa.

Dr. WILHELM EBSTEIN (Göttingen) said that **gout** was more or less chronic, and **depended on a hereditary diathesis** which was almost always congenital, and to which the name of uric acid diathesis had been given. The close relations which existed between uric acid and the nucleins rendered it probable that in the uric-acid diathesis there was an abnormal state of the cellular nuclei or of the protoplasm of the individual in question. The individual predisposition, which could be followed through whole families and successive generations, was a very important feature of the uric-acid diathesis. A variety of conditions seemed to contribute to the development of the uric-acid diathesis and to its transformation into actual gout, some of them being as follows: (1) all the circumstances being equal gout manifested itself earlier and with more severity when the uric-acid diathesis was well marked than when it was not; (2) personal habits, such as idleness and luxurious living, or the combination of these two in a high degree, or the abuse of alcohol, favored the development of gout, and temporary variations might very often be attributed to those conditions; (3) certain acute and chronic toxic influences in presence of the uric-acid diathesis favored the development of gout, among which some bacterial toxins were of great importance, and the relations of gout to rheumatism, syphilis, lead-poisoning, and influenza, must be kept in mind; and (4) neither contagion nor climate had any influence as regards gout. It was probable that it was only the uric acid formed at the expense of the nuclein substances of the human body, and not that formed at the expense of the nucleins of the food, which had an influence on the pathogenesis of gout. It was not yet proved that in gout uric acid was formed in excess; Dr. Ebslein considered that an increased formation of it was not indispensable, but was nevertheless very probable. In order to understand the pathogenesis of the different symptoms of gout it was necessary to presume the existence of primary articular gout and primary renal gout. The former was the commonest variety of gout, and did not prevent the patients from attaining an advanced age. Primary articular gout developed itself at first under the influence of retained uric acid, this retention being localized because it affected only a single part or some parts of the human body. In primary renal gout there was from the outset a generalized retention of uric acid which affected all parts of the body, and was always caused by primary structural disease of the kidneys.

SIR DYCE DUCKWORTH (London) concluded as follows: 1. Gout is a morbid condition dependent on an inherent vice of nutrition which was manifested by an imperfect metabolism in various organs or parts of the body, presumably in the kidneys and probably in the liver. 2. This trophic disorder or inadequacy (*ralentissement de nutrition*) led to the formation of uric acid, probably in excess, and to the periodic retention of it in the blood (**gouty urichemia**). 3. Histology threw no light upon the intimate nature of this defect which thus related to cellular potentiality, possibly under neurotrophic influence, and not, so far as was known, to structural alteration. 4. This textural disability or a tendency to it might be primarily acquired and also transmitted as a fault, thereby inducing from time to time urichemia with gouty manifestations in the descendants. 5. In most instances under conditions which provoked it, and in some cases independently of these, attacks of gout might grow up and come to a crisis. Such crises were attended by an alteration in the solubility of the uric salt in the blood whereby irritating crystals of sodium biurate were produced and precipitated in various parts of the body. 6. A paroxysm of gout, the sites of its occurrence, and its metastases, were determined

by nervous influences, probably dominated from the bulbar center, and the local attacks alighted either in the joints or in textures which had been weakened or rendered vulnerable by impaired nutrition owing to past injury or overuse. 7. This central neurosis was an essential and transmissible feature in the pathogeny of gout and pertained to the arthritic diathesis generally. 8. The urichemia of gout was peculiar and unlike that which was induced by other morbid conditions, but the occurrence of urichemia in the gouty was by itself inadequate to induce attacks of gout. 9. Uratic deposits in any part of the body might be removed in course of time, but were apt to be permanent in the least vascular tissues. 10. Uratic deposits might occur to an enormous extent in gouty persons without the occurrence of any pain or paroxysms. 11. The clinical features of gout indicated that both *hemic* changes (due to inherent morbid tissue metabolism) and a *neurotrophic disturbance* acted as pathogenic factors, and consequently gout was to be regarded as a neuro-humoral malady.

DR. CH. ACHARD and DR. S. LAACHE read papers upon **Diagnosis of renal insufficiency**. Dr. Achard dealt chiefly (1) with the results of cryoscopy applied to the urine and blood-serum, an index of the permeability of the kidney being thereby obtained, and (2) with the conclusions to be drawn from the elimination of a foreign body (usually methylene-blue) in the urine. Dr. Laache said that treatment ought to be prophylactic by preference, but if that was impossible the well-known methods of treatment in kidney disease ought to be followed. Special attention must be given to the state of the heart.

DR. ALBERT MATHIEU (of the Hôpital Andral, Paris), DR. F. BOAS (Berlin), and DR. JULIUS MANNABERG (Vienna) read papers upon **Mucomembranous colitis**. Dr. Mathieu said that constipation, often spasmodic, was the rule in mucomembranous colitis. Diarrhea, which was always of short duration, was the result of an attack of catarrhal colitis. There was always in mucomembranous colitis a secretional irritation of the mucous membrane. The disease only showed itself in its full intensity in persons predisposed by previous neuropathic tendency. Nervous derangement produced hyperesthesia of the walls of the large intestine and interfered with its motility. In treatment, castor oil, copious enemas, and belladonna were useful. Drastic purgative, astringent injections, and massage should be avoided.

Dr. Boas said that the only positive diagnostic symptom was the existence of the characteristic mucous masses; other symptoms, such as tenderness of the colon, coloptosis, movable kidney, and intestinal atony, went no further than supporting the diagnosis. It was absolutely necessary to decide whether the mucomembranous colitis was idiopathic or a complication. Differential diagnosis was required only as between mucomembranous colitis and colitis mucosa. By frequent observations and the systematic employment of intestinal injections a decision would be almost always possible. The clinical history of mucomembranous colitis was exactly parallel to that of habitual constipation, and methods of treatment which were suitable for the one were also suitable for the other.

Dr. Mannaberg said that a distinction must be drawn between enteritis membranacea and colitis mucosa. By the former name was understood a subacute or chronic catarrhal affection of the large intestine accompanied by evacuations particularly rich in mucus. Colitis mucosa was the name of a morbid condition characterized by paroxysmal attacks of colitis followed by the evacuation of masses of mucus. The former variety was, in fact, only a catarrh of the large intestine, accompanied by an abundant evacuation of mucus; it had in a general way the same pathogenesis as catarrh of the large intestine. Colitis mucosa had, on the contrary, a special pathogenesis. In the great majority of cases its basis was a general neuropathy (hysteria or neurasthenia) and there was a tendency to consider it as a neurosis. The paroxysms might be induced by certain factors of occasional occurrence, the principal of which were diseases of the genital organs (both in the male and the female), mental disorders, constipation, irritating rectal injections, and organic diseases of the intestine. The pathologic anatomy of enteritis membranacea was the same as that of enteritis in general.

PROFESSOR BASCH (Vienna) read a paper upon **Pulmonary edema**. He said that the primary pathogenic condition of pulmonary edema was the stoppage of the

capillary circulation in the alveoli from the increased blood-pressure in the left auricle. The second was that there was a free supply of blood from the right side of the heart coming through the pulmonary arteries. The mechanical consequences of these two conditions were the enlargement of the pulmonary alveoli and the increase of the resistance of alveolar walls. The enlargement was produced by the lengthening of the capillary vessels and the increase of resistance by the high tension of the blood in the capillary network. To these two consecutive processes might be added exudation into the alveoli, a natural consequence of the impeded circulation in the lungs. The enlargement of the alveoli and the increase of resistance in their walls created a mechanical obstacle to respiration and a consequent impairment of the aeration of the blood, giving rise to the sensation of dyspnea, which was only the expression of the disproportion between the respiratory effort and its effect. This morbid sensation was aggravated proportionately to the increase of carbonic acid which accumulated in the blood through the interference with its aeration. It overstimulated the respiratory centers and threw the respiratory muscles into forced action. The difficulty became greater when intraalveolar exudation was added to the preceding conditions of enlargement of the alveoli and increase of resistance in the lungs. Mere exudation without concomitant enlargement did not interfere with respiration so much as was believed. Persistent dyspnea increased the carbonic acid in the blood, and death of the heart from general asphyxia was the result. Cardiac dyspnea, cardiac asthma, and pulmonary edema had their starting point in muscular insufficiency of the left auricle, and not only in primary insufficiency which was characterized by low arterial pressure, but also in secondary insufficiency which was characterized by increase of the arterial pressure.

PROFESSOR MASIES (Liège) said that edema was an abnormal accumulation of lymph, and that acute pulmonary edema was only a particular variety of it presenting two peculiar characters depending on the activity of the pathogenic process and on its special situation; these were (1) the accumulation of fluid in the lymphatic tissue combined with the more important symptom that fluid collected in the alveolar cavities either by rupture of their walls or by exudation through them; and (2) the suddenness with which the phenomena appeared. The theories of the pathogenesis of this edema regarded in a general way were three in number: (1) the purely mechanical theory which attributed the edema to a great increase in the lateral pressure in the capillary vessels and which ought to be rejected; (2) the opinion of Hamburger and Heidenhain which considered that lymph was secreted by the endothelial cells of the capillary wall and that edema was an exaggeration of this function; and (3) the theory of Starling, Winter, and Théaulon, which ascribed the genesis of edema to modifications of the osmotic relations between the liquids on each side of the vascular wall and to variations in the permeability of this wall. Two prominent facts had here to be considered. In the first place, an active, simple, noninflammatory hyperemia of the vessels without obstacle to the flow of liquid was by itself incapable of producing edema. In the second place, lesions of the capillary walls, involving an increase in their permeability, were an important factor in edema. Clinically pulmonary edema occurred in three forms: 1. *Inflammatory edema*, which was probably a reflex vasodilation, developed under the influence of some causal factor and followed by a direct lesion of the walls by microbes living in the interior of the normal pulmonary parenchyma. 2. *Edema of stasis*, which was by far the most frequent and was met with in diseases of the heart, especially in commencing stenosis, in diseases of the vessels such as aortitis or arteriosclerosis, and in diseases of the kidney such as primary sclerosis. Much experimental work had been done on this subject, but the conclusions were often contradictory. The fact which appeared best established was that edema might be produced under the influence of an increase of pressure in the pulmonary arteries arising from an increased activity of the right ventricle concomitant with a stasis due to inaction of the left heart. 3. *Toxic edema*, which was hardly known except in experimental research, examples being the edema produced by muscarin and by iodine.

M. TEISSIER (Paris) said that acute edema or serous apo-

plexy of the lung must be distinguished from the varieties of pulmonary edema, the evolution of which was generally slow or chronic, and which had a mechanical or passive origin. The special nature and different origin of acute edema were indicated by its sudden onset and by the absence of fibrin in the effused fluid. Clinically it was distinguished by premonitory sensations of tickling in the throat or painful intrathoracic tension and by intense dyspnea, accompanied by continuous spasmodic cough and soon followed by frothy-red expectoration, with abundant fine rales to be heard over the edematous region. For its production either infection or the previous action of a toxic agent was necessary. Among infective conditions, acute articular rheumatism, influenza, puerperal septicemia, typhoid fever, and pneumonia held the first place. The requisite toxic action was exercised chiefly by Bright's disease and by alcoholism. This preponderant influence of infections and of toxic influences was proved by experiments on the artificial production of pulmonary edema by means of muscarin, prussic acid, salicylate of methyl, nitrite of amyl, and even by the injection of salt-solution. Heart-disease was another important factor. Acute edema of the lung was distinguished from passive and chronic edema not only by its pathogenesis and symptoms, but by the fact that these two varieties of pulmonary edema have a totally different prognosis, acute edema being often extremely dangerous and capable of causing the death of the patient in a few hours. With regard to treatment, experience had shown the undeniable value of blood-letting. Atropin had given only negative or untrustworthy results. Morphia was dangerous and ought not to be employed.

PROFESSOR DIEULAFOY (Paris) made a report upon **gastric ulcer**. He did not take into consideration all the symptoms and all the complications of gastric ulcerations, but selected a few types, including (1) erosion, which was the smallest of the ulcerations but might nevertheless lead to copious hemorrhage; (2) lesions of the mucous membrane somewhat larger than erosion, and for which he proposed the name "exulceratio simplex"; (3) simple ulcer (*ulcus simplex*), the most formidable complications of which were hemorrhage and perforation; and (4) specific ulcerations of the stomach due to tubercle and syphilis.

PROFESSOR A. JACOBI (New York) read a paper on the **Artificial feeding of infants**. Results of the analyses of human milk were contradictory, no two were alike. Alterations in different periods of lactation which were asserted by some were denied by others; those caused by menstruation, sickness, or ingesta were either well understood or dimly appreciated, but rarely measurable. The nature of its proteid, whether uniform or compound, was not sufficiently known. Whether there was an essential quality that was beyond the domain of chemistry was not known. That was why so many and so different ironclad rules had been established for the selection of substitutes and why the uncertainty had rendered experimentation with commercial substitutes by chemists, and even by respectable clinicians, so common. If human milk were a uniform body the demand for an exactly equivalent substitute would be justified. Nature, however, was more liberal in allowing latitude than a chemist. Heat both improved and injured milk. When milk was exposed to from 68° to 70° C. for 10 or 15 minutes the *Bacterium coli* and the *Bacillus lactis aerogenes* were destroyed; after long exposure this heating killed pathogenic germs; at 80° C. it coagulated albumin and changed the taste and odor of the milk; even at 70° C. it changed casein so as to impair its value for dairy purposes. In boiling, a part of the albumin was deposited, the lecithin was destroyed, and the fat was altered both chemically and physically. Sericus changes appeared to take place through long boiling, both in casein and in nuclein. High temperatures continued for hours were required to destroy some of the long-lived spores; their injuriousness, however, was not entirely clear. Boiled, pasteurized, or sterilized cow's milk was never woman's milk; it was not a curative agent; it afforded, however, the great advantage of destroying fermenting and pathogenic germs; that was why it was indispensable in large cities and during the prevalence of certain epidemics, and wherever fresh and unpolluted milk was not accessible. When employed as exclusive infant food cow's milk watered or not was liable to cause constipation, or diarrhea, rickets, and scurvy.

The mineral constituents of cow's milk and human milk

were different. The addition of chlorid of sodium to artificial foods was required both for physiological and chemical reasons. Home made artificial foods were preferable to the proprietary foods of the market for many reasons. The separation of the component parts of cow's milk by mechanical means and the recombination of the same was a procedure of doubtful value. The experience of the physician and of the well-directed public at large was equivalent at least to laboratory and library theories based on facts that were *sub judice*.

DR. O. HEUBNER (Berlin) said that a scientific set of rules could not be drawn up for the artificial feeding of children, except by a study of the healthy infant born at full time. As rules for feeding a healthy workman could not be laid down by the study of a diet of an invalid, so a normal infant could not be fed by studying the difficulties or successes obtained in feeding unhealthy children. This, however, was what medical men very generally did, because they were so constantly brought into relation with invalid children. The common sense of nurses, however, had always understood that nothing could replace the milk of the mother so well as the milk of some animal. The milk of the various domestic animals, especially that of the cow and of the goat, did not differ more from the milk of a woman than the various sorts of meat differed the one from the other, such for instance, as pork and beef, which the healthy child, like the adult, could eat alternately. The intestine of the healthy infant was capable of digesting the milk of the cow just as well as the milk of a woman. The labor of digestion, however, was greater in the former case than in the latter, for large proteid molecules required a greater digestive effort than the small hydrocarbon molecules, and cow's milk was very rich in the former, while the milk of a woman was rich in the latter. Other difficulties of artificial feeding arose from infection or decomposition to which the milk of an animal was always exposed before the child got it. As regards this danger, the sterilizing of milk was one of the most important advances made during this century.

DR. MONTE (Vienna) read a paper upon the **Scientific principles involved in preparing from the milk of an animal an equivalent diet to the milk of a woman**. He pointed out that the acidity of cow's milk could be reduced to that of the milk of a woman by the addition of carbonate of potassium. Coagulation should be arranged so as to take place in the same manner in the milk of the cow as in the milk of a woman. To do this, equal quantities of cow's milk and of buttermilk should be mixed together and a little carbonate of potassium added. The proportions of casein, of fat, and of sugar could all be arranged to be in the proper proportion by the use of a mixture of milk and buttermilk.

DR. AXEL JOHANNESSEN (Christiania) read a paper upon the **Sterilization of milk and mode of use**. He pointed out that to sterilize milk completely by boiling at the ordinary atmospheric pressure it would be necessary to cook it for several hours; but sterilization could be carried quite far enough by other methods, of which the best and simplest was pasteurization at 70° C. Great care should be taken to look after the milk-supply so that the supply of raw milk should be as free from germs as possible. The milk after pasteurization should be cooled down to about 17° C. and used within 12 hours.

PROF. A. BAGINSKY (Berlin) read a paper upon the **Gastro-intestinal affections of children from the point of view of pathological anatomy**. These he divided into: I.—Functional troubles comprising acute dyspepsia, not marked by any important anatomical changes. II.—1. Anatomical alterations: (a) lesions of a catarrhal nature, such as subacute dyspepsia, accompanied by cellular infiltration of the mucous membrane; (b) infantile cholera with destruction of the intestinal epithelium over a large surface; (c) chronic gastrointestinal catarrh; and (d) intestinal atrophy. All these latter processes—namely, from a to d—were accompanied by vomiting, diarrhea, and colic. Assimilation was impaired, and the functions of the liver and pancreas were disturbed. 2. Anatomical lesions localized in the follicles. These might be divided into (a) simple follicular enteritis accompanied by a moderate degree of fever, a slight pain, and the secretion of blood; and (b) severe infectious follicular enteritis. In this there was destruction of the mucous membrane and the formation of abscesses. III.—Both functional

troubles and the more severe morbid processes were due to infection or intoxication produced from within. Such were the action of the normal microbes of the intestine, the virulence of which was exalted under particular circumstances. They could also be produced from without by the influence of toxins derived from the food, or by microbes introduced with the food which became virulent in the intestine, or finally some poison might be contained in the food. IV.—Those morbid processes, which were most often developed during the heat of the summer, were caused by the common saprophytes or their toxins, but these microbes were not specific. Septicemia arising from the intestine was very rare. Cases had been reported where the infection had been localized in the kidney, and where the infarct had gone on to suppuration or necrosis.

DR. MARFAN (Paris) read a paper upon the **Causes of gastroenteritis in infants**. He said that dyspeptic gastroenteritis arose mainly from improper feeding, that infectious gastroenteritis was principally caused by germs in the milk of the cow being conveyed into the digestive tract. Toxic gastroenteritis resulted from the introduction of some chemical poison into the digestive tract. Poisoning by drugs was not uncommon, but the usual source of poisoning was milk, due to its containing toxins which had been produced by the action of germs before sterilization. Other kinds of gastroenteritis were consecutive to various maladies, such as, for instance, measles, influenza, or diphtheria. Infantile cholera or summer diarrhea seemed to be due to a combination of circumstances—namely, some alterations in the digestive secretions set up by the hot weather which brought about a kind of self poisoning, the increased growth of microbes in the milk of the cow under the influence of high temperature, and, finally, the formation of microbes of toxins before sterilization.

PROF. D'ESPINE (Geneva) read a paper upon **Prophylaxis in infantile tuberculosis**. He said: 1. Infantile tuberculosis was a parasitic affection acquired by contagion in the child in the same way as in the adult. There were, however, exceptional cases in which the affection was congenital, being acquired by way of the placenta. 2. The source of the contagion in the immense majority of cases was from the sputum of tuberculous adults. 3. Another source of contagion was by way of the milk of cows, or very occasionally of goats, which were suffering from tuberculosis of the mammary gland. This mode of infection played a more important part in the infant than in the older child. 4. In infants up to the age of 2 years kissing by their mothers or nurses who were affected with phthisis appeared to be the usual mode of transmission. Sometimes contagion was carried directly by aspiration into the bronchi of saliva which contained bacilli. 5. In the child of between 2 and 6 years of age tuberculosis was very frequent and, as a rule, commenced in the bronchial glands. The greater frequency of tuberculosis between the ages of 2 and 6 years was explained by the habit which children had of putting everything in their mouths and of sucking their fingers. 6. From the age of 6 years up to that of puberty the frequency of tuberculosis commenced. There was a very real danger of contagion owing to the circumstances of school life, but in D'Espine's opinion this danger had been exaggerated. 7. The infection of tuberculosis occurring through the skin was very exceptional. 8. Hereditary predisposition played an important part in the production of tuberculosis in the child. It was therefore necessary that prophylactic measures should be specially applied to the children of tuberculous parents. Measures of prophylaxis might be divided into two classes—namely, those which went to diminish the danger of contagion and those which raised the resistance of the child to the infective organism. In the first class measures directed towards giving the child a supply of healthy milk might be included. Precautions must be taken that the nurse under whose care the child was placed should be free from tuberculosis. If the mother was phthisical the infant must be suckled by a healthy nurse. If the child came of a tuberculous family the general prophylactic measures recommended by the Academy of Medicine must be attended to. In schools no phthisical person should be allowed to be either a master or a mistress. Measures for raising the resistance of the children were as follows: The building of homes in the country to which poor and weakly children could be sent. Holiday camps should be provided for scholars, and any predisposition to tuberculosis in its

earliest manifestations should be fought against by sending children either to some mountain station or to the sea.

DR. HUTINEL (Paris) read a paper on **Heredity in tuberculosis**. Tuberculous heredity might show itself in three ways—by a transmission of the germ itself, by transmission of the predisposition, or in various nutritive trouble. 1. (a) Transmission of the germ at the time of conception was at present nothing more than a hypothesis; and (b) it was possible, however, that the fetus could be infected before birth through the placenta. 2. Heteromorphic heredity. 3. Hereditary predisposition. 4. Prophylaxis. From the point of view of prophylaxis the part played by the medical attendant was very important. He should pay special attention to—1. The protection of tuberculous children against infection by bacilli. 2. In tuberculous children one great danger to be guarded against was the existence of latent centers of tuberculosis which were capable of giving rise to autoinfection. 3. In phthisical children all troubles incident to growth should be carefully attended to where there was any suspicion of a predisposition to tuberculosis.

Surgery.

PROFESSOR CECCHERELLI (Parma), in speaking of **pancreatic surgery**, arranged his conclusions under 24 headings, of which the following were the principal: (a) Emaciation, presence of fat in the feces, sugar in the urine, bronzed skin, jaundice, and pain, were met with in the majority of pancreatic affections. (b) Complete extirpation of the pancreas was difficult on account of its deep situation and its intimate connection with important viscera rich in vessels and nerves. (c) Surgical intervention was more justifiable at the small end of the pancreas than at the head. (d) Extirpation should not be attempted in cases of tuberculous or syphilitic lesions. In partial extirpation one of the two canals must be left. (e) Pancreatic tumors were generally either blood-cysts following injuries or retention-cysts. In the latter case surgical intervention was useful, but should be limited to excision of the cyst. It was necessary to keep in mind the question of opening Wirsung's canal and the probable discharge of pancreatic juice into the abdominal cavity. (f) Pancreatic calculi might be extracted. (g) Necrosed fragments of the pancreas might be removed. (h) In suppurative or gangrenous pancreatitis the rule was to do nothing during the acute stage. For the treatment of abscess or gangrene of the pancreas three routes were available—the lumbar extra-peritoneal, the transpleural, and the median supraumbilical. (i) In hernia of the pancreas caused by injuries reduction and even fixation might be performed. (j) In contusions and wounds of the pancreas, if there were hemorrhage it might be arrested either by sutures or by tying the bleeding vessels. Clots of blood in the abdominal cavity should at the same time be removed. (k) Experimental pathology justified the fixation of movable pancreas. (l) If from any cause the duct between the pancreas and the duodenum became closed a new passage might be made for the pancreatic juice, or a pancreatic fistula might be established. (m) Stitches through the pancreatic parenchyma did no harm, and were tolerated as in the kidneys, the liver, and the spleen. (n) In suturing the pancreatic duct the stitches should not pass into the interior of the duct, as concretions were liable to be formed on them. (o) Regeneration of the pancreas had been observed. (p) After complete extirpation of the pancreas great development of the glands of Galeati had been observed, and especially a karyokinetic increase in the epithelia, leading to the supposition that the missing gland might be thereby replaced. (q) The thermocautery or galvanocautery ought not to be used in extirpation of the pancreas.

MR. MAYO ROBSON (Leeds) commenced his report on the same subject by stating that he was convinced that pancreatic affections were much more common than was usually thought. He based his remarks on his personal experience, he having operated on 40 cases of pancreatic disease and having seen a considerably larger number of cases in which operation was either not consented to or not thought advisable. Under "anatomical considerations" he dwelt on the importance of posterior drainage, where practicable, in acute and in suppurative pancreatitis. For reaching the main pancreatic duct he had found it practicable to incise the second part of the duodenum and lay open the termination duct from the papilla. In over 50 cases which he had

seen he had found cancer usually to occur after 40 years of age, and he believed that the cases occurring earlier in life were in many instances chronic interstitial pancreatitis, which might resemble cancer not only in the symptoms but in the naked-eye appearance after death.

He believed **chronic interstitial pancreatitis** was often mistaken for cancer of the head of the pancreas, and which he believed had not received much attention either from clinical observers or from pathologists, certainly not as much as it deserved. His experience in this class of cases had resulted from his having operated on a considerable number of cases of jaundice depending on obstruction in the common duct, the obstructive jaundice, wasting, paroxysmal attacks of pain and ague-like seizures having given rise to the suspicion of gallstones and the absence of relief by medical treatment having rendered surgical treatment necessary. He argued that its recognition was of vital importance since it was a disease not only capable of relief but of absolute cure by surgical treatment.

DR G. MANOURY (Chartres) said that in order to lessen the chances of **erroneously interpreting the appearances shown by radiography** it would be desirable to mark certain data on the photographic plates, especially the point where a perpendicular drawn from the focus to the plate met the latter. Radiography had rendered great service in the diagnosis of fractures by revealing the number of the fragments, their form, their position, the overlapping of their ends (which when the photograph was well taken corresponded with sufficient exactness to the shortening of the limb), their displacement in different directions, and the position of splinters. For the purpose of gaining an accurate knowledge of the nature of a fracture it was necessary to take radiographs of it at different angles, usually a front view and a side view. It was possible for a fracture to be unrecognized, even though the bone was examined in various directions; this, however, was very rare. Radiography was useful in all fractures. Among those in which it was most valuable the following might be mentioned: fractures of the upper extremity of the humerus, which so often produced stiffness and ankylosis attributed to periarthritides; fractures of the lower end of the radius, which frequently accompanied lesions of the carpus; fractures of the leg, especially those involving the articulation of the tibia and the tarsus, in which last radiography was the only means of obtaining exact information as to the relations of the astragalus, tibia, and fibula, a matter of great importance in the prognosis and treatment of these fractures; fractures of the astragalus, which were some years ago erroneously considered to be very rare; and, finally, fractures of the metatarsal bones, the anatomical lesion of a condition well known to military surgeons, the cause of which had for a long time been discussed without its real nature being suspected. The formation of callus might be studied by means of radiography. At the end of 12 days there appeared at the ends of the bones a slightly shaded area which became gradually darker. In certain cases, especially in oblique fractures of the tibia, the callus might remain invisible for a long time, even after consolidation appeared to be complete. Radiography was as useful in the treatment of fractures as in their diagnosis, facilitating reduction, and enabling the position of the ends to be inspected, and, if necessary, corrected, during the process of consolidation. Radiography also showed in what fractures wiring was required, examples of which were to be found in fractures of the elbow and ankle. Radiography had not done so much for dislocations as for fractures, but a certain number of unrecognized dislocations had been diagnosed by this means. Unfortunately, it gave no information as to the most frequent causes of irreducibility.

PROF. E. VON BERGMANN (Berlin) said that the **knowledge of fractures** had during the last ten years made two important advances—firstly, the operative treatment of certain simple fractures by the exact apposition of the fragments, and secondly the recognition of the seat of fracture and of the pathological anatomy of the osseous lesions by means of radioscopy and radiography. Without doubt there were manifest local causes which hindered the consolidation of fractured surfaces. It was known, for instance, that the interposition of muscular fibers prevented the formation of callus in cases of fractured femur. Unfortunately, it was not possible by means of the Röntgen-rays to make sufficiently sure of this to warrant the making of an incision.

DR. OSCAR BLOCH (Copenhagen) argued that from a practical point of view **every wound** without exception ought to be **considered to be infected** and that infection and its complications were due to the retention of secretions containing microbes. Antisepsis and drainage ought therefore to be the rule, and in order to avoid reinfection the wound ought to be dressed rationally. Carbolic acid was, he said, the best antiseptic, and the best applications were sterilized gauze dressings containing aqueous solutions of carbolic acid, and cotton-wool. He had little confidence in internal antiseptic treatment, in febrifuge treatment, or in serum treatment, including the use of antistreptococcus serum.

DR. FELIX LEJARS (Paris) said that every accidental wound ought to be treated as an infected wound, even though no indications of such infection might be presented. The treatment ought to consist in careful cleansing at as early a period as possible, assisted if need be by excision, care being taken not to impair the vitality of the cells which form the natural defence of the living tissues and which have to be assisted in their protective actions. Sterilized water, artificial serum, and sterilized or boiled compresses fulfilled all requirements under this head. Antiseptic solutions were injurious when concentrated, and when diluted to such an extent that they did not interfere with the protective cells their action was in reality only a mechanical and cleansing one. Suppurating wounds should be exposed to the air, cleansed, drained, and dressed with some absorbent material. In cases of infected wounds, whether suppurating or not, specific serum treatment was indicated, but their resources in this respect were unfortunately very limited; antitetanic serum was only a prophylactic; antistreptococcal serum had been employed chiefly in puerperal infection and erysipelas. In some foul and gangrenous wounds oxygenated water was useful. In certain cases artificial serum treatment aided the natural resisting power of the organism, increased the blood-pressure, and promoted diuresis.

DR. ROUX (Lausanne) said that **intestinal anastomosis by lateral apposition** was the most practicable of these procedures. Anastomosis was preferred in cases of numerous adhesions, of inoperable tumors, and of certain inaccessible inflammatory conditions, such as tubercle and actinomycosis. It was a preliminary operation in cases of operable tumors occurring in very feeble patients and in cases of pyostercoral fistula it was often quite successful. Gastroenterostomy, on account of its being less dangerous, preceded pylorotomy if the state of the patient rendered it desirable. In nonmalignant disease of the pylorus and stomach, for which an easy evacuation of the gastric contents was required, gastroenterostomy was preferable to pylorotomy and pyloroplasty. It was much superior to gastrotomy and gastropexy.

DR. SOULIGOUX (Paris), said that in the treatment of cancer and stricture of the bowel **intestinal anastomosis** was most usually the principal operation, or it might be a complementary operation. In cases of acute or even of chronic obstruction of the bowel the formation of an artificial anus was to be preferred. When there was retardation of the onward movement of the feces without obstruction, if there was a movable tumor which could be easily removed, enterectomy ought to be performed, but this operation ought to conclude with an anastomosis either latero-lateral or termino-lateral. If the tumor was adherent anastomosis was the only available operation. For cicatricial stenosis of the pylorus, or of the first portion of the duodenum, or for hour-glass contraction of the stomach, gastroenterectomy was the best operation.

PROFESSOR HOFFA (Würzburg) read a paper upon **Cutting operations in congenital dislocation of the hip**. He pointed out that in cases of this deformity the operation without the cutting was the one to be preferred. The cutting operation which was the best for children of from 3 years up to 8 was that in which a new cavity was made for the head of the femur by the operation after the manner invented by Hoffa and Lorenz. The best time for it was between the ages of 3 and 8 years. That surgeon would succeed best who was able to carry out complete asepsis. The wound need not be stitched. The after-treatment was of the greatest importance as the muscles were thereby strengthened. Ankylosis did not occur except when the wound suppurated and when the operation was done at too advanced an age.

DR ADOLPH LORENZ (Vienna) then read a paper upon the

Bloodless treatment of congenital diseases of the hip-joint. This treatment, he said, was to be preferred to the operative, for the latter was not without its dangers (2% to 10% mortality, according to different statistics). The ankyloses and contractures, which frequently followed, required a tedious after-treatment. The injury to, or the extirpation of, the Y-shaped cartilage of the acetabulum might result in subsequent deformity of the pelvis, on account of disturbances in development. Among the bloodless methods the treatment by means of portable apparatus could be said to be without limit; but, as a rule, without result, in spite of this fact. The gradual reduction of the head of the femur by means of bed extension was only successful in very young children. The treatment was tedious and the confinement of active children in extension beds was detrimental to their general health. The bloodless reduction under narcosis overcame all the difficulties. Under the proper age-limits it was entirely without danger. These limits were, for unilateral dislocations, the ninth or tenth year; for double dislocations, the seventh or eighth year.

DR. KIRMISSON (Paris) read a paper on the same subject. The principal point upon which he insisted was that the displacement should be reduced by means of an extension apparatus, and that the position thus obtained should be maintained by the use of an apparatus which should keep the limb in the same position as those employed in the treatment of ordinary disease.

DR. ROUX (Lausanne) read a paper on the **Therapeutic indications in appendicitis**. Purgatives should be absolutely forbidden throughout the whole course of the disease. Even during convalescence they should be replaced by enema. The patient should not be moved if it could possibly be helped. Opium might be given or an injection of morphia. Ice might be applied to the seat of the disease; only caution must be used and warm applications should succeed the cold. As to the indications for operation, if the diagnosis was certain and if it was made within the first 24 or 36 hours, which very rarely happened, an operation at this stage was no more dangerous than an operation done *à froid*. After 36 hours—and this time had generally elapsed before any medical man and especially the surgeon had been called in—the operation of Dieulafoy might be carried out. Just as an operation would be quite justified if performed early, so it was uncertain in its results and often dangerous if performed during the intermediate period. But if the fever and the pain and the rapidity of the pulse persisted operation was justifiable. It was also justifiable when the fever became hectic and it was undoubtedly indicated if the patient had attacks of shivering or if the pulse kept very rapid while the temperature fell. By the surgeon attending to these rules it was possible that he might let a few patients die who were suffering from the septicemic form, but he would avoid killing a great number of others.

DR. JALANQUIER (Paris) said that every appendix which was diseased should be excised and the operation should be practised *à froid*—that was to say, when the general phenomena of infection had disappeared and when the local lesions had lost their activity. Too much hurry in operating exposed the patient to the risk of disturbing the favorable course of the disease, for the acute stage of appendicitis generally terminated by a localization of the lesion and by its resolution when it was treated from the beginning by rest, careful diet, ice, and opium. Too hasty intervention was liable to give rise to another danger—that was to say, it was quite possible to operate upon the patient who had not got appendicitis but some of the diseases which simulated it. The only reason for intervention during the acute stage was to empty the abscess of its septic contents, and to drain it very freely. In cases of very chronic appendicitis giving rise to frequent acute crises resection of the appendix was in most cases sufficient to effect a cure. In some cases, however, it would be found necessary not only to remove the appendix but to divide various bands, to free coils of intestine, or to resect portions of omentum which had become chronically inflamed.

DR. KÜSTER (Marburg) said that **renal retentions** could be divided into two groups: (a) Primary retention—i.e., cystic or sacculated kidney; and (b) secondary retention—i.e., suppurating kidney, of which he should say no more, as that condition almost invariably called for a radical operation. The term "sacculated hernia" was applied to all

the instances of primary retention produced by any obstacle to the flow of urine, whatever be the contents of the sacs. As a general rule these obstacles were situated in the ureter and almost invariably in its upper third. Renal retention due to some obstacle in the renal pelvis should be treated by a conservative operation—i.e., the affected kidney should be preserved even if the other kidney was healthy. Conservative operations might be divided into four groups: (a) Fixation of a displaced kidney (nephropexy of Guyon). This simple operation must be combined with others, such as detachment of the ureter. (b) Formation of an anastomosis between (1) one part of the ureter and another, (2) the renal pelvis and the ureter, and (3) the renal pelvis and the bladder. All these operations should have for their end the avoidance of dead spaces, which were conducive to the formation of urinary calculi. Without this precaution the procedure was harmful. (c) Plastic operations with or without resection of the ureter. 1. Pyeloptychy (Israel). 2. Excision of valvular formations in the ureter and transverse suture (Fenger). 3. Resection of a kink in the ureter. Oblique resection was preferable to transverse, which might only lead to the formation of a fresh stenosis. 4. Ureteropyelostomy (Trendelenburg and Küster). (d) Partial resection of the kidney. 1. Resection of the pelvis with suture (Albarran). 2. Wedge shaped section of the renal substance in cases of hydronephrosis occurring in a horse-shoe kidney.

DR. CHRISTIAN FENGER (Chicago) said **remittent or commencing retention of urine** was a condition in which they should always consider the possibility of saving kidney-tissue by reestablishment of the free passage of the urine. The obstruction might be located in the calyces, in a branch of the ureter, in the bottom of the pelvis, or origin of the ureter, or in the ureter. Obstruction in the first two places caused a local or partial cystonephrosis and demanded for the relief of the condition bisection of the kidney from its convex surface and division of the partition walls. Stenosis at the exit of the ureter (valve-formation, oblique implantation from unilateral dilation) required operations which varied in accordance with the absence or presence of stricture at the upper end of the ureter. If there was no stricture at the upper end of the ureter the valve-formation might be overcome by a transpelvic operation (Fenger, Mynter, Trendelenburg, Küster), or by extrapelvic operation, which he preferred. If there was a stricture of the ureter at its exit from the pelvis, as might be expected in infected cases, they might resort to extrapelvic plastic operation (Fenger), or to resection of the strictured end of the ureter, implantation of its upper divided end into the pelvis (Küster). If the stenosis or obstruction was located in the ureter it must be dealt with according to the laws laid down for surgery of the ureter—namely, resection and reimplantation, or Dr. Fenger's plastic operation. Were the results of these, so to speak, tentative conservative operations permanent, or did relapse eventually occur? In five of his cases no relapse occurred. The conditions were as follows: 1. Valve-formation; transpelvic operation; no relapse six years later. 2. Stricture at the upper end of the ureter; extrapelvic operation; no relapse six years later. 3. Valve-formation of lower branch of the ureter; extrapelvic operation; bisection of kidney, division of partition walls; no relapse after three years. 4. Excision of valve in the ureter by Dr. Fenger's plastic operation; no relapse after three years. 5. Stone in upper end of the ureter removed by Dr. Fenger. One year later a plastic operation on the ureter was performed by another surgeon. Six months later complete occlusion of the ureter at the site of the second operation was relieved by Dr. Fenger's plastic operation; no relapse after one year. In two cases relapses occurred under the following conditions: 1. Valve-formation without stricture, intrapelvic operation, relapse of stenosis, occlusion of pelvic orifice; nephrectomy one year later. 2. Patient operated on by another surgeon, later by Dr. Fenger; operation was incomplete, failed, and nephrectomy was finally necessary.

PROF. A. VON FRISCH (Vienna) read a paper upon **The remote effects of operative treatment in hypertrophy of the prostate**. He said that of all the various operations for hypertrophy of the prostate only those which had for their object the complete removal of that portion of the prostate which prevented the free flow of urine offered any chance of lasting success. Such were subpubic and

perineal prostatectomy, lateral prostatectomy, and Bottini's operation. The effects of all these were the more lasting in proportion as the passage was freed and remained free from cicatrization. Operations done under the eye evidently answered best to these conditions, and such were the different prostatectomies. But they were always serious undertakings on account of the age and general feebleness of the patients in whom they were required. Bottini's operation was less dangerous, but not so free from risk as some would have them believe. Both classes of operation gave good and lasting results, even when the bladder was dilated and its muscular wall was apparently partly paralyzed; a good result will follow if the obstruction be completely removed. However, no precise line of conduct could be laid down so as to assure success. The lasting effect of all these operations might be discounted by the formation of the new scar tissue or by a new hypertrophy of the gland.

DR. F. LEGUEU (Paris) said that there were three classes of operations: (1) operations on the testicles; (2) cystotomy; and (3) prostatectomy. 1. Of these, operations on the testicles sought to bring about atrophy of the prostate. In lieu of castration, which was considered by some to be too severe, division of the vas deferens or section of the vessels and nerves of the cord had been proposed. But all these were inferior in value to castration. As regards the remote results of double castration they were not so good as the early observations which did not take a long enough space of time into consideration would have had them believe. The prostate certainly shrunk, but the patient improved to a far greater degree than could be accounted for by the diminution observed. The attacks of pain were less frequent and the contractility of the bladder improved so that the residual urine was less in quantity. But, after all, there was only amelioration and not permanent cure, and comparing the results of castration with those of other methods it was doubtful whether the advantages of it were worth the sacrifice. 2. Cystotomy sought to make a meatus above the pubes. It doomed the patient, however, to incontinence of urine and the bladder could never empty itself completely. 3. Direct interference with the prostate appeared to be more and more the operation for the condition of hypertrophy. Bottini's operation could not yet be fairly judged from the point of remote results. Besides, it was done in the dark and patients often relapsed owing to the new passage closing up again. Partial prostatectomy gave excellent results in partial hypertrophy, but was of no use where the prostate was uniformly enlarged. Total prostatectomy could give very good results, and apparently if undertaken by the perineal route at an early enough date before grave complications had set in seemed to be the operation of election for hypertrophy.

Obstetrics and Gynecology.

DR. DOLÉRIS (Paris) read a paper on the **Etiology and nature of puerperal septicemia**. The ordinary pathogenic germs found in puerperal septicemia were the streptococcus, staphylococcus, gonococcus, and *Bacillus coli communis*. Researches had shown that amongst the pathogenic organisms certain anaerobic forms, such as the *Bacillus putridus*, must be included. A further conclusion was that some saprophytic anaerobic organisms could develop and act as true pathogenic germs, notably in cases of placental retention. The association of different species led more certainly to infection. The septicemic condition caused death from toxic poisoning, which produced either nervous inhibition or intestinal paralysis. The staphylococcus might cause death by visceral metastasis. The theory of autogenesis had recently received a new interpretation, according to which the pathogenic organisms existing in the pathological vaginal secretions should not be considered as saprophytic, and since autogenetic infection could not be distinguished from that due to saprophytic organisms this amounts to denying its existence.

DRS. MENGE and KRÖNIG (Leipsic) understood **puerperal fever** as a malady of the puerperium in which pathogenic organisms infected the body as a whole. Fever might be entirely absent. They were unable to distinguish between the organisms which acted purely by their toxic properties and those which penetrated the tissues, nor could they distinguish with certainty between a fever due to one or the other.

The organisms causing puerperal fever were: *Streptococcus pyogenes puerperalis*, *staphylococcus*, *gonococcus*, *Bacillus coli communis*, *Bacillus diptheriae*, *Diplococcus pneumoniae*, and certain imperfectly known organisms developing in the absence of oxygen, since they found them in puerperal lesions. The infection could be either autogenetic or heterogenetic. Gonorrheal puerperal fever should be regarded as due to the spread of an infectious process already existing in the body, not as an example of autogenesis. As the various organisms mentioned did not exist as saprophytes in the vaginal secretions of pregnant women an autogenetic infection by these organisms could not have as its seat of origin the vaginal secretion. Infection with anaerobic bacteria could not be denied since they were unable to distinguish with certainty between the anaerobic organisms causing puerperal fever and the anaerobic saprophytic organisms present in the vaginal secretion of pregnant women. Clinically they regarded as rare and of favorable prognosis an infection due to pathogenic organisms of saprophytic character derived from the skin of the external genitalia. The possibility of a puerperal infection being caused by organisms present as saprophytes in the cervical canal, the cavity of the uterus, or the tubes could be rejected since these cavities never contained such organisms. With regard to heterogenetic infection the number of germs undoubtedly present was a matter of importance. The difficulty in attempting to determine the varying degrees of virulence of different organisms was very great. They could only say that when an organism had lived a saprophytic existence for some time that its virulence was greatly diminished. Insufficient hemostasis and marked lesions of the genital tract played an important part as predisposing factors. The primary seat of infection was most commonly the placental site or the endometrium; much less commonly the cervix, vagina, or perineum. The streptococcus had a great tendency to spread beyond the primary seat of infection either by the lymphatics or bloodvessels, while the staphylococcus often remained limited to the endometrium.

DR. RIBEMONT-DESSAIGNES (Paris) read a paper on **The treatment of the apparent death of the newly-born**. As a result, he said, of numerous causes which might occur during its birth the child might when born, present the appearance of apparent death. Two varieties of asphyxia occurred, the blue and the white, while at times cases were met with in which both forms were present at the same time. Since in practice asphyxia was most commonly due to obstruction of the air-passages by mucus or amniotic fluid charged with meconium it was necessary to (1) free the air-passages, and (2) to facilitate the entrance of air into the lungs. As the mucus frequently only occupied the throat it was often sufficient to clear it out by means of the finger wrapped in a handkerchief. Cutaneous friction with or without alcohol, ether, brandy, eau de cologne, warm baths, mustard baths, hot or cold baths were often sufficient to excite respiratory movements. Rhythmical traction on the tongue might set up respiratory reflex. If these procedures failed it was necessary to commence artificial respiration. Of the various methods available insufflation was the only one that fulfilled the two conditions necessary, viz., to clear the air-passages and to facilitate the entrance of air. And, further, the insufflation should be instrumental. The apparatus employed should admit of aspiration of the foreign matters present, and it should not carry into the lungs a quantity of air greater than their capacity. To fulfil these conditions the instrument must be constructed upon anatomic principles. The insufflator formed upon the model introduced by him in 1877 fulfilled the necessary conditions. (1) Its introduction was easy owing to its curve and the shape of its end; (2) its curve assured its remaining in the air-passages; (3) it prevented the reflux of air from the larynx; (4) it readily permitted of the aspiration of the fluid and mucus filling the bronchial canals; (5) it was easy to determine whether it was in its right position or not; and (6) the bulb attached permitted only of a quantity of air entering sufficient to distend the lungs without over-distending them.

DR. RICHELLOT (Paris) read a paper upon **The treatment of cancer of the uterus**. Total extirpation of the uterus by the vagina was, he said, a rational method, because it enabled them to deal completely with the disease and to get entirely beyond its limits. It was a relatively benign operation, the mortality of the reporter amounting to about 6%.

It was a most efficacious operation. Ott had had cures extending over 12, 11, 10, 8, and 6 years; Landau after 9½, 8, 7, 6, 5, and 4 years; LeDentu and Pozzi after 6 years; Quénu, Terrier and Hartmann, and Routier after 5 years. The speaker had had cases alive 12½, 12, 10, 9, 8, 6, 4, and 3 years after operation. Making all allowances he was able to show at least 18 per 100 who had been definitely cured. The improvement that had occurred in technic had led to a revival of the operation of abdominal hysterectomy. Equally to be condemned were those surgeons who advocated extensive operations of this kind both for cases of cancer where the disease had spread beyond the uterus and those who recommended them in cases where the disease was still limited to that organ, with the proviso that in either case such an operation enabled them either to remove all the affected tissue or to make sure of being well beyond the limits of the disease. No true comparison could be made between cancer of the breast and cancer of the uterus and it was impossible even by such an operation as abdominal hysterectomy to make sure of removing all the affected tissues. Cancer was primarily local and secondarily infective. A microbic origin for the disease was as yet unproved. Personally he was led to consider cancer as a trophic lesion independent of external causes. One proof amongst others was heredity and another the relation between cancer and arthritic troubles. A hundred times he had seen cancer and arthritic troubles transmitted, coinciding or alternating in such a fashion as to convince him as to the pathologic family in which they should be placed. It should, undoubtedly, be the aim to operate at a time when no cancerous cell had progressed beyond the limits of the uterus. If they succeeded in doing this and in removing all the morbid growth then they might well speak of a definite cure, and they might even neglect the predisposition of the organism to reproduce another cancer. The proper treatment of cancer at the present day was to anticipate its spread and not to attempt to overtake such spread once it had begun. And, indeed, the organism itself came to their assistance. Intervention was not always without avail even when it appeared to be a little late. Such cases were difficult to recognize. It was justifiable, however, to adopt the abdominal operation in the presence of a limited spread of the cancer to the vaginal wall, rendering a vaginal operation impossible, but not indicating any real diffusion of the cancer. The operation was also justifiable in the presence of a tumor of slow growth the course of which they had been able to follow for some time. In such cases he had adopted abdominal hysterectomy without regarding it as a sovereign remedy and duly recognizing its limitations. He had endeavored to show that vaginal hysterectomy was capable of obtaining definite cures and that abdominal hysterectomy was a useful recourse in a small number of cases, but that applied to cancers which had already become diffused it was an imprudence, and to cancers still very limited an illusion. That was to say, he differed from those who saw in the first an operation always incomplete, merely palliative, and in the second, the only operation which removed all, the only operation which was logical and rational. He would say that that operation was truly curative which preceded the cancerous infiltration—that which pretended to pursue it was really merely palliative.

DR. DMITRI DE OTT (St. Petersburg) came to the following conclusions on the same subject: 1. Surgical treatment was the only successful method of combating cancer of the uterus. 2. The peculiar functions and structure of the uterus required a special study of the cancers that attacked it. Conclusions drawn from cancer in other parts of the body were only applicable in certain special cases. 3. Total extirpation of the uterus should be practised in all cases of cancer of any part of the organ, since the procedure gave the greatest amount of success. Removal of the ovaries and appendages should only be practised under special conditions. Removal of the retroperitoneal glands could only be carried out by the abdominal route. This method should not be practised as a rule since it was much more dangerous and the results were not sufficiently good. Total extirpation by the vagina was to be preferred to all other methods. Morcellement in the cases where the uterus was of large size or the case complicated by the presence of fibroids was a method of great value. In cases of pregnancy complicating cancer of the uterus vaginal extirpation should still be carried out. The

operation could be practised up to the seventh month and after opening the culdesacs and ligaturing the uterine arteries the size of the organ could be readily reduced by the removal of the ovum. If the pregnancy was still further advanced and the child viable the latter might be delivered by abdominal section and the uterus, if practicable, removed by the vagina. It was best not to close the peritoneal opening but to lightly plug it with iodoform gauze. The ultimate results of operation undertaken for cancer of the body were much better than those undertaken for cancer of the cervix. Total extirpation should be practised even in advanced cases, since it tended to alleviate the condition of the patient, and especially in view of the difficulty of making an exact diagnosis of the extent of the disease. The mortality of the operation should not exceed 2% and the proportion cured with no sign of recurrence after 6 years was 10%, extirpation having been practised even in the most advanced cases.

DR. S. POZZI (Paris) read a paper introducing **Cervical metritis**. His conclusions are as follow: 1. Acute or chronic inflammation of the cervix could exist for a long time isolated and without invading the body of the uterus. 2. At times the acute lesions of the cervical mucous membrane readily invaded the mucous membrane of the body, and the chronic lesions of the cervical parenchyma of inflammatory origin (sclerotic or sclerocystic degeneration, partial or total) in a short time produced some effect upon the nutrition and the anatomic condition of the body of the uterus. 3. The operation of trachelorrhaphy was inferior to biconical resection of the cervix and should be abandoned. 4. A large number of acute, subacute, or chronic inflammations of the cervical mucous membrane in nullipara were due to insufficiency of size of the external os uteri and the difficulty of drainage that resulted. The most important part of the treatment consisted in restoring by operation to a sufficient extent the patency of the external os.

DR. DOEDERLEIN (Tübingen) followed, saying that at the present day the causes of inflammatory diseases of the cervical canal and of the cavity of the body of the uterus were to be found in a microbic infection. Modern bacteriologic researches had shown that the external os uteri formed a boundary between a lower part of the genital tract containing microorganisms and an upper containing none. The alkaline cervical mucus proved destructive to organisms introduced from without and so formed a protection not only to the cervix but to the body of the uterus, the tubes, and the peritoneal cavity. Among pathogenic organisms the only two that played any important part in the production of cervical metritis were the gonococcus and the tubercle-bacillus. Gonorrheal infection of the cervix was very common, the means of defence of the cervix being unavailing against the gonococcus, but tuberculous infection limited to the part was very rare. Tuberculous, syphilitic, and diphtheric lesions of the cervix were quite different from so-called cervical metritis.

Cancer of the Rectum in the Female.—Wallace K. Oakes (*Journal of Medicine and Science*, April, 1900) reports a case of cancer of the rectum in a woman 46 years old, and describes an operation which he thinks indicated in cases in which the patient is a female, and the cancerous growth is above the sphincter and below the sigmoid. In this case the growth was 2½ inches up in the bowel, and completely encircled the rectal canal. The sphincter was dilated and the rectum attacked by cutting directly through the vaginal floor, beginning 2 inches above the vaginal outlet. The incision was carried through the perineal tissues and into the rectum, the latter being laid open from this point and through the sphincter. The rectal tube was dissected away from the surrounding tissues, the section containing the cancerous growth excised, the upper segment pulled down and sutured to the lower segment containing the sphincter. The rectal, perineal, and vaginal tissues were then approximated by sutures. The patient has recovered, having complete control of the sphincter. There is as yet no sign of recurrence, although but a few months have elapsed since the operation. A woman with a cancerous rectum was treated similarly, in 1892, by Oakes; she lived for one year, and then died of cancer of the stomach. There was no sign of recurrence in the rectum. [M B T.]

2.—Pye-Smith thinks if **medical science** without art is inefficient, **medical art** without science is not only unprogressive, but almost inevitably becomes quackery. As soon as we treat our patients by rule of thumb, by tradition, by dogmas, or by metaphysical axioms, we do injury to ourselves as well as to them. Our profession has often suffered from lack of the scientific, inquiring, skeptical spirit, and has often been led too easily by authority, by tradition, and by fashion. The reckless abuse of venesection in the last century and the former half of this led to almost complete disuse of a valuable means of treatment; the misuse of mercury in the treatment of syphilis led to denial of its unquestionable efficacy. Have we not seen the value of stimulants in a contest with fever lead to their indiscriminate use in almost every ailment? Has not the immense value of careful and thorough nursing sometimes ended in its exaltation to an independent place, as if good nursing was anything more than an intelligent carrying-out of the physician's directions? Have not the remarkable powers of electrical stimuli led to a blind, unscientific, and mischievous employment of this remedy, as if it had some mystic efficacy apart from its demonstrable physiological effects? May we not say the same of hydropathy, of massage, of hypnotism? That important and constantly growing branch of medicine, which deals with the **prevention rather than the cure** of disease, depends no less upon science, for tracking the dependence of one event upon another is the essence of inductive science. All efficient measures for the preservation of health, whether by individuals or communities, rest upon exact knowledge of the natural course of diseases. In fact, disease may be defined as the reaction of the human organism under conditions which make for its destruction. How closely natural science is related to preventive medicine is shown by the history of Jenner, who was a naturalist, and Pasteur, who was a chemist. How dependent we are upon science is well illustrated by the history of myxedema. Contrary to popular belief, he holds that modern life is easier, safer, and smoother than it was 100 years ago, that our young men and maidens are healthier, stronger, better grown, less emotional, less hysterical, and sounder in mind and body than their great-grandparents, and he holds that the duty of a physician is not to flatter the selfishness of **neurotic patients**, but to inspire fortitude, and to prescribe regular and steady work as the best cure for a thousand nervous ailments. There is one aspect of scientific medicine so important that it must not be wholly omitted; the necessity of **experiments** for the progress of pathology, and through it for the prevention and cure of disease. It requires no argument to convince anyone who is the least acquainted with the principles of inductive science that experiment is no less necessary than observation. The foolish cry against hospitals as places where they experiment on patients is meaningless just because it is true. Every prescription we give either to rich or poor is an experiment, and should be watched with critical and scientific eyes. And is it not a mistake for so many of us to prescribe the **made-up drugs** offered us by wholesale manufacturers instead of our own combinations? It leads our patients to ascribe their recovery not to our skill, but to this or that pill or tablet. It would be an excellent task for this great Association

to set some of our skilled analytical chemists to strip the veil from mysterious remedies and tell us the exact composition of the many patent medicines, some of which are inert, and some injurious. [A.B.C.]

3.—Murray and Hardcastle report the case of a single man of 29, who complained of loss of power and sensation in both lower limbs. There was a history of exhaustion and wetting while passing water-buckets at a fire in the country, which was followed by lumbar pain and cold and numbness in the legs. The condition grew worse and was accompanied by retention of urine and loss of control of the rectum. On admission to the hospital the patient complained of girdle-pain, loss of motion, and sensation below the umbilicus, and preservation of these functions above that point. The reflexes were abnormal; there was a bedsore over the sacrum; the urine was acid, had a foul smell, and contained blood and pus; and the temperature was 103.4°. The condition became progressively worse and the patient finally died, 7½ weeks after the commencement of his illness. Permission for a necropsy could be obtained only on condition that the vertebral canal alone be opened. The surface of the dura mater was covered with lymph, and bacteriologic examination was made of the exudate as well as of the pia mater, and of the substance of the cord on a level with the fourth or fifth thoracic nerves and at the lumbar enlargement. A short, oval, motile bacillus was obtained from the cultures and was found in stained specimens of the cord. The organism stained readily by the anilin dyes with a polar staining; it was stained by Gram if care was used; it produced a rapid general infection in the guinea-pig and a local infection in the rabbit; it grew readily on the ordinary media, both in the hot and the cold incubations; and it liquefied gelatin. The value of the bacteriologic examination is lessened by the fact that the bedsore communicated with the vertebral canal, but the authors believe the organisms did not come from that lesion. This case is valuable as evidence that **acute meningomyelitis** is an infective disease. [J.M.S.]

4.—Williamson describes anew his **reaction of diabetic blood**. Forty cmm. of water are placed in the bottom of a small, narrow test-tube. To this are added 20 cmm. of blood, 1 cc. of a watery solution of methylene-blue (1:6000) and 40 cmm. of liquor potassæ. The test-tube is then placed in boiling water for 4 minutes, at the end of which time, if

the blood is diabetic, the blue color of the mixture will have disappeared and a dirty yellow color will have taken its place. The reaction has been obtained in all of 43 cases of diabetes. The author's experiments indicate that the reaction is due to the excess of glucose contained in the blood. The reaction is of value when, as in diabetic coma, urine cannot be obtained, or when a patient has died of diabetic coma and the bladder is empty so that the urine cannot be examined. The reaction can be obtained even when the body has been long dead. [J.M.S.]

5.—Home believes that **scurvy** is essentially an infection of the mouth with microorganisms out of decayed food, antagonized by lime-juice and fresh vegetables which act as antiseptics. This infection of the mouth is most apt to occur in times of hardship when cleanliness is least within reach. [J.M.S.]

7.—Bird makes several suggestions with regard to the technic of operations for the **radical cure** of oblique inguinal **hernia**. He believes that incision far down toward the pubes is unnecessary, and advises a skin incision fully an inch above Poupart's ligament. He considers the deep layer of the superficial fascia a tissue of considerable value. There is no occasion to strip it from the aponeurosis, but it may be dissected back with the aponeurosis and used as an accessory layer of moderate but undoubted restraining power. The external ring can be separated with less damage than to divide the fibers. If we divide the ring, Bird believes that no suture can make it so strong as before. The division of the aponeurosis he makes one or two inches beyond the internal ring. Any cutting of the fibers of the internal oblique is considered a mischievous procedure. He advises elimination of the sac from above with preservation of the nerves. Not all hernias are susceptible to treatment in this way, but the results are practically perfect when such an operation is possible. [M.B.T.]

8.—The paper treats of several drugs in use in India that may subsequently be found of use in England. [J.M.S.]

9.—Warden mentions 3 methods of **treating the stump of the appendix** which he designates as follows: the continental method, used by most Paris surgeons, cauterizing the stump and leaving it open in the abdomen; the English method, turning back a collaret of peritoneum and stitching it over the ligated stump; and Doyen's method of ligature, removal with the thermocautery and invagination and the application of purse-string suture. The last he considers the best method, and he believes that it originated with Doyen. [Warden has probably overlooked the fact that practically the same method which he describes as Doyen's has been in use in America since 1891, when it was introduced by Dabarn. The method has been used and described by several American surgeons since that time. [M.B.T.]

10.—Meggitt reports 2 cases of **pernicious anemia** that were treated with Hommel's hematogen with good results. The first patient was a man of 35, and the second was a woman of 38. [The cases are incomplete, as a complete record of the histologic examination of the blood is not presented, without which the diagnosis of pernicious anemia should not be positively made. J.M.S.]

11.—A case of sudden death, probably from heart paralysis, is reported following an operation for adenoids and enlarged tonsils with chloroform-anesthesia. [M.B.T.]

12.—A boy entered the hospital with symptoms of tumor of the brain. An operation was begun, but not completed on account of cessation of respiration. The patient was kept alive by **artificial respiration** for 4 hours. The necropsy showed a **tumor** of the left lobe of the **cerebellum** which was thought to be tuberculous. [M.B.T.]

6. Some Observations Upon the Ocular Symptoms in Locomotor Ataxia. PAUL TURNER VAUGHAN.

7. A New Hypnotic. WARREN B. HILL.

1.—Porter says that **congenital dislocations of the shoulder** are very rare. A large majority of those which do occur are due to traumatism at birth. One must differentiate between these traumatic cases and those due to imperfect development. This is necessary because of the great difference in the treatment and prognosis. He quotes Scudder as saying that a point to remember in differential diagnosis between these two classes is that if the condition is due to imperfect development at the articular surfaces there will be also a difference of development between all the bones of that extremity and the normal one. The various "obstetrical paralyses" due to injury of the cervical nerves at birth may be confounded with congenital dislocation. After a careful study the author draws the following conclusions: 1. It is of fundamental importance to discriminate between traumatic and developmental cases. 2. The pathology of the congenital cases is not sufficiently known to indicate the most promising line of treatment. 3. Sufficient operations have not been done to establish a successful method of operative treatment or add much to our pathological knowledge. 4. In cases determined to be developmental by the history and measurements, remembering the probable deficiency of development of the one, or both articular surfaces, an early operation, before the humeral head has formed a new articular facet under the spine and has itself become deformed, offers the best results. [A.B.C.]

2.—Whitehead, after a study of the action of **gelsemium on the nuclei of the motor cerebral nerves**, concludes that toxic doses of this drug produce chromatolysis of the cells constituting those nuclei and that the changes are not specific, but are similar to the changes caused in motor nerve-cells by various other noxious agencies. [J.M.S.]

3.—In the **treatment of the morphin habit** the patient should be kept in bed, or at least in the recumbent posture, during the rapid reduction of the drug. When a patient is taking large doses of morphin the greater part of the dose can be left off at once with little discomfort, because the system makes no use of much of the dose taken and will, therefore, not miss it. The patient should be allowed to recover from one reduction before a second is made. The last reductions should be quite small and if much suffering or depression is caused by a reduction it is sometimes better to return to the former dose until the patient has recovered from the shock. A patient should not know the details of his treatment. During the period of reduction the feeling of uneasiness and pain in the limbs may be relieved by frequent hot baths and massage, which should be given at least once a day. Bromids are the best drugs to quiet the nervous system, but bromism should never be produced. Quinin, coca, nux vomica, or strychnin are the best tonics. Sleeplessness may be combated by chloralamid, trional, or hyoscyamus. The quitting of the taking of the drug is but part of the cure, the moral, the physical, and the mental condition of the victim must be built up. The majority of morphin habitues are men lacking in self-control. [J.M.S.]

4.—In the treatment of **enterocolitis** Fitch recommends calomel for unloading the bowel. He gives one grain of the drug every hour for 3 doses to a child 2 years old. He recommends tannopin for its action as an intestinal antiseptic, which he uses both by the mouth and as a rectal injection. The histories of 5 cases are given. [It would seem as though calomel, since it is a drug that is not readily absorbed, is recommended in too large a dose. Powders containing $\frac{1}{4}$ grain of calomel repeated every hour until 10 are taken will be found to do the work just as well as those containing the larger dose. J.M.S.]

5.—Oppenheimer says **suprarenal extract** has 2 distinct actions on the mucosa of the respiratory tract; it blanches the tissue, and at the same time constricts it. The blanching effect is not so great in the larynx and pharynx as in the nasal cavities. The drug acts only on mucous surfaces, and its influence is absolutely local, no tissues are affected except those in contact with the drug. In epistaxis, due to minor traumatism, visceral changes, such as the heart, lungs, or liver, or the result of local affections of the nares, immediate benefit is observed on spraying the interior of the nose. The local application in hay fever often does much

good, but he thinks it does no good when given internally. It dissipates swelling following operations in the nasal cavities. It is of value in secondary bleeding, and in local congestions, either acute or chronic. It is especially useful in all operations in the upper respiratory tract. The spray alone is often not sufficient. The author's mode of application is as follows: The parts to be operated upon are covered with a pledget of cotton saturated with the adrenal, which is allowed to remain for 5 minutes. This is removed, and a solution of cocain or eucain of whatever strength desired is applied in the same manner for a similar length of time. This is also removed and a fresh piece of cotton with the adrenal solution is again pressed against the tissues for another 5 minutes, and when this is removed it will be found that the parts are perfectly bloodless and totally anesthetic. The operation can then be readily performed. The duration of its effect depends much upon the method of application. The majority of cases will show some anemia of the mucosa from 1 to 5 hours after the application of the drug. It has no anesthetic influence, but it tends to prolong the anesthesia of cocain when combined with that drug. This is accomplished by preventing hemorrhage and the consequent loss of the cocain from the tissues. The drug has no effect upon the blood; it is nonirritating; it can safely be placed in the hands of the patient; and it may be repeatedly used in the same individual without losing its effect. It is contraindicated in anemic processes and in conditions in which the mucous membrane possesses a low degree of vitality. [A.B.C.]

6.—Vaughan has treated 18 cases of *tabes dorsalis* in the past year, in which *eye-symptoms* were observed. Ten of these were private patients, and a careful record was kept of them. Of these 10, 40% had paralyzes of the eye-muscles, 60% had inequality in the size of the pupils, 40% had reflex rigidity of the pupils, and 50% had atrophy of the optic nerve. Six of the 10 cases had a combination of eye-symptoms. Nine of the 10 cases had been infected with syphilis. One patient had symptoms of bulbar paralysis combined with paralysis of the ocular muscles. The most constant pupillary change was the Argyll Robertson pupil. All the cases began with disturbance of the color-sense, and contraction of the visual field. The author agrees with Peterson, who remarks that "while syphilis is an antecedent in three fourths of tabetic cases, the syphilitic resemble the non-syphilitic cases as regards the histological characters of the lesions, and specific treatment has no effect whatever upon the cases with syphilitic history; hence the malady is not a syphilitic disease, not a direct sequel of syphilis, but that the venereal disorder prepares the constitution like a cachexia for the development of the degenerative process." [A.B.C.]

7.—Hill believes that *chloreton* is the ideal hypnotic. It produces sleep as nearly as possible as it is produced by the fatigue of muscular action, it produces the least amount of irritation to the alimentary canal, and it does not depress the circulatory system or the glandular secretions. It is useful in cases in which morphin has lost its action, and it is an ideal remedy in delirium tremens. It is a local anesthetic, and as such is useful in removal of the tonsils, in anesthetizing the mucous membrane of the nose, in anesthetizing the urethra, and in relieving pain after strong injections for cystitis. It is useful as a local anesthetic in dental operations, and in minor surgery. It is also an antiseptic. The dose is from 15 to 20 grains, and it may be repeated often enough to produce the desired effect. [J.M.S.]

Medical Record.

August 18, 1900. [Vol. 58, No. 7.]

1. Extrabuccal Feeding. C. A. EWALD.
2. Migrated Ovarian and Parovarian Tumors. GEORGE M. EDEBOHLS.
3. Posterior Colpoceliotomy for Lesions of the Adnexa and Uterus; Its Indication and Technic. CHARLES GREENE CUMSTON.
4. Hematomyelia, with Report of Three Cases. W. F. BECKER.

1.—Ewald discusses the 3 forms of feeding that may be employed when the introduction of food through the esophagus is impossible. These are nutritive enemas, subcutaneous or intravenous injections of foodstuffs, and feed-

ing after gastrostomy. He does not believe that any of these methods are capable of supporting life, but under favorable conditions, it is possible by them to maintain a nutritive balance of metabolism. In **rectal feeding** it must be remembered that the secretion of the large intestine is probably devoid of all peptonizing power, but is, nevertheless, capable of digesting moderate amounts of albumen as a result of the admixture of pancreatic secretion. It is therefore necessary to use some predigested mixture, such as the Leube-Rosenthal pancreatic meat enemas, and experiments have shown that when these are employed, almost the entire amount of nitrogen is absorbed. Pepton may also be used, but under certain circumstances even small quantities will produce marked evidence of irritation. Ewald and Eichhorst have shown that native albumen in the form of egg emulsion is readily absorbed even after preliminary peptonization, and this seems to be particularly useful in enemas. In addition to albumen and milk, it is necessary to supply some carbohydrates and the best of these is probably grape-sugar. As much as 95% of this is absorbed from solutions not too concentrated. Starch decoctions may also be employed with benefit. Fat may also be added and is particularly valuable in economizing calories. It is necessary, however, to mix it with pancreatic bile-substance in order to obtain any satisfactory degree of absorption. Ewald suggests the following as perhaps the most valuable nutritive enemas: Two table-spoonsful of wheat, stirred into 150 cc. of lukewarm water or milk. To this two eggs and a pinch of salt are added, and then the whole is mixed with from 50 to 100 cc. of a 15% to 20% solution of glucose. To this a small amount of alcohol, specially in the form of claret, may be added. When nutritive enemas fail to fulfil all the requirements of the case, **subcutaneous or intravenous injections** may be employed. For this purpose neither albumen nor carbohydrates can be used, but fat can be given with very satisfactory results. The best oils for this purpose are ordinary butter and olive oil. From 100 to 150 cc. may be injected at a time through a hollow needle with a small lumen. Injection should be made very slowly, as much as 1 to 2 hours being required for the quantity stated. There is more or less pain produced, which may last for a long time even if massage is also employed. Unfortunately in these injections, no water can be employed, and this is often more important than food. **Feeding through a gastric fistula** if it has been produced for nonmalignant stricture, may cause no alteration in nutrition. In malignant cases it may be necessary to use predigested foods. [J.S.]

2.—Edebohls designates as **migrated ovarian and parovarian tumors** such growths as have by torsion and tension of the pedicle become entirely detached from their former connection with the broad ligament, and either lie free in the abdominal cavity, or have formed new attachments to other organs or tissues. He reports 4 cases: 1. A gangrenous monocyst removed from the omentum, the growth having all the characteristics of a parovarian cyst, though no trace was left of its former attachment. 2. Large, strangulated, left parovarian cyst free in the abdominal cavity, its pedicle having been completely severed by torsion, and the left ovarian ligament and tube pulled out of the uterine cornu. 3. A self-amputated, left ovarian cyst which, in twisting itself free, carried with it the greater part of the left tube. The contents had escaped and been absorbed with a part of the cyst wall, the remainder becoming adherent to the back of the uterus and left broad ligament, thus maintaining its vitality. 4. Dermoid cyst of the right ovary which had probably become completely detached at the time of a peritonitic attack some years previous to the operation at which time it was found engrafted upon and completely wrapped in the omentum from which it drew its sustenance. Recovery followed operation in all these cases. [W.K.]

3.—Cumston advocates **posterior colpoceliotomy** for lesions of the adnexa and uterus. After quoting the statistics of Schauta and Teplor, he answers the various objections. To the objection that it is a slow method, he replies that though in a small proportion of cases it takes some time to draw the adnexa down and form a proper pedicle, the operation may be performed in from 20 to 30 minutes. To the assertion that clamps placed on the pedicle act as a serious hindrance, he says that unless adhesions are extensive, clamps should not be applied until the pedicle has been formed and ovary and tubes are ready to be removed, and

then ordinarily 1 pair is sufficient; rarely are more than 2 needed. He advises the use of an exaggerated Trendelenburg position as giving the best field of vision and one which is quite sufficient. If there is really lack of space to perfect the operation, a very rare occurrence, 2 lateral incisions in the perineum should be made as in obstetrical practice to permit the passage of the head. The vagina can be rendered quite as sterile as the abdominal wall and the antisepsis of the whole operation just as perfect. The danger of ventral hernia is avoided, and persistent fistula is less likely to result, and, if it occurs, is far less annoying to the patient. Anterior colpotomy is useful in certain cases, as tumors situated on the anterior wall of the uterus; also the 2 ways may be combined. The lesions which may best be removed by posterior vaginal incision are: Inflammatory affections of the adnexa with prolapsus in the culdesac of Douglas; cysts of the adnexa of small dimensions; neoplasms which are situated high up in the pelvis, but which are movable and can be drawn down; large cystic tumors, provided that they are not adherent, and that by digital examination through the vagina the finger can readily reach the lower pole of the neoplasm; solid neoplasms of the rectouterine culdesac which do not exceed the breadth of the posterior vaginal culdesac; extrauterine pregnancy. Contraindications are, extensive adhesions, a very high position of the adnexa or of the uterus with the impossibility of drawing them down within reach, and the malformation of a very tight vagina. Under these conditions the abdominal incision should be chosen. [W.K.]

4.—Becker records 3 cases of **hematomyelia**. After a preliminary discussion of the symptoms of this disease and of spinal localization, he describes the first case, that of a woman of 30, who suddenly felt faint and sank to the floor. There was immediate paralysis of the legs that soon became complete and was flaccid in character. She developed bedsores and cystitis, and although subsequently able to move the foot slightly, she finally died of exhaustion. The woman was slightly anemic. The most probable cause was an abortifacient whose nature was unknown. The second patient, a man of 38, alcoholic and syphilitic, fell and was found to be paralyzed on the left side. Later the right side also became paralyzed. In the course of 38 hours the patient died of paralysis of the respiratory muscles. At the autopsy a small amount of blood was found extending from the middle of the fourth to the middle of the sixth cervical segments. It occupied chiefly the ventral horns of the gray matter and was greatest on the left side. The third patient, a young woman, without any previous medical history, suddenly had pain in the back and found her legs extremely weak. In the course of an hour they became completely immovable. Paralysis of the bladder and rectum occurred. Next day there was some improvement, and in the course of 4 months only stiffness of the movements, increase of the knee-jerks, particularly of the right side, and some atrophy of the right leg. The electrical reactions were diminished, quantitatively, but there was no degeneration. In the course of time she became perfectly well. There was practically no disturbance of sensation in this case. It is difficult to understand the nature of the lesion because the gray matter appears to have been only slightly involved. [J.S.]

Medical News.

August 13, 1900. [Vol. lxxvii, No. 7.]

1. The Treatment of Acute Alcoholism by Large Doses of Digitalis. HENRY P. LOOMIS.
2. Subsequent Histories of Patients Apparently Cured Under Administration of Antitubercle Serum as an Auxiliary to Climatic Treatment. J. EDWARD STUBBERT.
3. Acute Anterior Poliomyelitis. E. D. BONDURANT.
4. The Treatment of Wounded at Sea. BELGRAVE NINNIS.
5. Some Problems in Rural Sanitation. JOHN C. THRESH.
6. Modern Pathology. E. E. KLEIN.
7. Tropical Diseases. Colonel KENNETH MACLEOD.
8. A Case of Double Vagina and Double Uterus: Four Pregnancies. HERMAN E. PEARSE.

1.—Loomis, following the suggestion of Fothergill, has treated 10 cases of **acute alcoholic delirium** with large doses of **tincture of digitalis**. A half ounce of this was

given every 4 hours for 3 doses. If the patient became quiet, the remedy was stopped even before the third dose. If not, a second series of doses was given 6 hours apart. There was no marked effect upon the pulse; the chief action apparently being narcotic. The results were that in 3 cases the patients recovered promptly, in 2 cases death occurred, 1 apparently the result of alcoholism, in the other the presence of petechial hemorrhages beneath the endothelium led to suspicion of infection. As a result of the study of all the cases which are reported at the end of the paper, Loomis concludes that the indiscriminate use of these large doses of digitalis is dangerous. They should be restricted to robust patients without complications. When no narcotic effect is produced by 3 preliminary doses the drug should be discontinued. It appears to be of least value in chronic alcoholism, in old patients, and in anemic patients; one good effect was the rapid convalescence that always ensued.

2.—Stubbert, in 1898, reported 36 cases of incipient tuberculosis of the lung that he had treated with **antitubercle serum as an auxiliary to climate**. He also reported 42 cases of advanced phthisis that improved and 4 far advanced cases with improvement. Of the 14 incipient cases apparently cured, he has been able to obtain the following subsequent results: 9 of these patients are still apparently perfectly well, they have no cough, no physical signs in the lungs and they are able to attend to their various occupations. In addition he reports 1 case from the moderately advanced group in which improvement has also occurred. He also reports 13 new cases which have only been out of the institution for a year. These all show persistent improvement and one of them is particularly interesting on account of the presence of tubercular keratoiritis which has shown a moderate amount of retrogression. He gives the following summary of all his figures: Of the patients out of the institution for 3 years 11% have remained cured; out for 2 years 14%; and out for 1 year 69%. He believes that antitubercle serum produces some immunity and that it is a valuable auxiliary to climatic influences.

3.—Bondurant discusses **anterior poliomyelitis**, which he regards as an infectious disease, although he is inclined to suspect that it may be produced by a number of microorganisms. He calls attention to numerous epidemics that have occurred, particularly one in the State of Alabama that he had the opportunity of studying himself. In this instance there were 15 cases occurring during the summer months confined to an area of about 12 miles in diameter. He gives a brief account of the symptomatology and calls attention to a few interesting points in differential diagnosis. He believes that the treatment should be limited to preventing contractures and deformities. He speaks of the excellent results reported by Sinkler after the administration of salicylates. [J.S.]

4, 5, 6, 7.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, No. 7.

8.—Pearse reports a case of **double vagina and uterus** which was of interest from the fact that for 16 years the woman, in ignorance of this deformity, had fulfilled the duties of wife and mother, bearing 4 children at term in comparative safety. When continued ill health after the fourth confinement led to an examination, the septa, both vaginal and uterine, had been almost obliterated by lacerations resulting from successive acts of parturition, and only remnants of the former condition could be found. [W.K.]

Boston Medical and Surgical Journal.

August 16, 1900. [Vol. cxliii, No. 7.]

1. Surgical Pain. G. RYDER.
2. The Psychic Factor in Disease. ROBERT W. GREENLEAF.
3. A Brief Report of a Case of Cerebral Abscess of Otic Origin; Operation; Death. GEORGE L. RICHARDS.
4. Purgation with Opium. J. W. WAINWRIGHT.
5. A Case of Volvulus Complicated by Peritonitis; Operation; Recovery. W. P. GIDDINGS.

1.—Ryder believes that many lives might be saved by a thorough knowledge of the **value of painful symptoms**, particularly in cases of acute abdominal disease. He calls attention to 3 great characteristics of inflammatory pain: that pain is elicited by pressure and is greatest as a rule at

the seat of inflammation; that movement even in the maintenance of the function of the part causes pain, and that the pain is accompanied by the disturbance of normal function. He discusses the various varieties and the characteristics of the pain of appendicitis, intestinal perforation, pelvic pain and the pain of various forms of intestinal obstruction. [M.B.T.]

2.—Greenleaf reports a number of interesting cases in which mental impression played a large part either in the disease or in its cure. He believes some cases of illness are merely neuroses and that some neuroses may be produced in association with organic disease. Moreover, **psychic causes may predispose to organic conditions.** He therefore insists that it is important to pay attention to these features of diseased states, and that in particular the nurse should be able to enter into psychic relation with her patient. Apparently he does not employ hypnotism, but believes in quiet admonition and careful study of the character of the patient. [J.S.]

3.—A man of 28 had had a discharge from the right ear 2 years previously and had been free from any trouble until 10 days before entering the hospital when he was taken with severe pain in the right ear and a slight discharge. Local treatment was given in the office and the patient was allowed to go to his home, but was found in a dazed condition and brought to the hospital. The right pupil was much dilated, the left was normal and the entire left side was paralyzed. The mastoid operation was performed, but the pathologic conditions found were not considered sufficient to account for the patient's condition, and the skull was trephined an inch above and behind the auditory meatus. A **brain abscess** containing 2 ounces of foul-smelling pus was found about a fourth inch beneath the cortex. This was evacuated, the cavity was washed with sterile water and a drainage-tube was inserted. Symptoms of bronchopneumonia developed after the operation. The patient grew rapidly worse and died on the third day after operation. A necropsy was not allowed. [M.B.T.]

4.—Wanwright reports the case of a boy of 5 who in order to escape detection swallowed suddenly a quantity of cheese. From that time he had **intestinal obstruction**, and it was believed the cheese had lodged at the ileocecal valve. After various laxatives and purgatives had failed, an operation was considered, but a consultant suggested the **employment of opium.** This apparently relaxed the spasm and caused free purgation. [J.S.]

5.—A boy of 15 while playing "snap the whip" was thrown for some distance and was afterwards taken with pain in his abdomen. His physician diagnosed intestinal obstruction, which was not relieved by high enemas and saline cathartics. Symptoms of peritonitis developed. On opening the abdomen bloody fluid escaped and a **volvulus** was found and untwisted a little below and to the left of the umbilicus. Rapid, uneventful recovery followed. [M.B.T.]

1.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, p. 1440.

2.—Knapp finds the use of the galvanocautery much superior to silver nitrate in treating **keratoconus.** He gives the following rules as to the manner of application: Never cauterize too deeply, and if the result of the first operation is imperfect, apply the convex disc electrode again to the place in which you want the subsequent cicatricial contraction to have the greatest effect. Spare, if in any way possible, at least half of the pupillary area. If we operate early, even in restricting as we should our interference to the progressive cases, we have to deal with a clear cornea, the reaction will be least, and the visual result as well as the operative effect greatest. We should not operate when the least septic condition is present in the conjunctiva or in the lids and surroundings of the eye, in particular in the lacrimal sac. [M.B.T.]

3, 4, 5.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, p. 1287.

10.—Cohen's experience with **thymus extract** does not agree with that of Cunningham and Svehla, who found that the thymus extracts depressed blood-pressure by a vasodilating influence. According to his clinical experience, the blood-pressure is raised and vasodilation corrected by the administration of the thymus gland. In the group of cases to which Cohen has called professional attention, under the name of vasomotor ataxia, 2 subclasses may be made; the one exhibiting greater tendency to undue relaxation of the vessels, and finding its extreme type in Graves' disease; the other exhibiting a more marked tendency toward undue contraction of the vessels, and finding its extreme type in Raynaud's disease. Between these extremes exist all varieties, often with commingling of diverse tendencies toward vascular instability. He believes in a physiologic antagonism between the thyroid and the thymus—at least so far as vascular constriction and dilation are concerned. While he has observed some gratifying recoveries following the use of thymus substance, with and without the adrenal substance, and in urticaria and asthma, and for the correction of the neurovascular disturbances of the menopause, he also records many failures. Whether the cause of the failure lies in the theory of therapy, in the diagnosis, or in further and undiscovered idiosyncrasies of the patient, it is impossible to say. [M.B.T.]

Centralblatt für Gynäkologie.

June 30, 1900.

1. A Case of Self-Expelling Large Fibroma. ORTO V. WEISS.
2. Total Vaginal Extirpation of a Ruptured Uterus During Labor. A. J. IWANOW.

1.—Weiss describes the condition of a woman brought into the hospital on a stretcher, who on examination showed a large cavity in the posterior vaginal vault covered with necrotic shreds of a tumor which had suppurated and been spontaneously expelled. A microscopic examination of the remaining fragments proved it to be a **true fibromyoma.** The history of the case indicated the presence of the tumor upon the posterior wall of the cervix previous to the birth of the last child, which had been a normal delivery. But the pressure at that time upon the tumor between the uterus and the pelvic wall had so injured its tissues as to cause necrosis and the exfoliation of the tumor, which began not long after, causing a very offensive discharge. The remnants of the tumor being removed by the physician, the patient rapidly recovered. [W.K.]

2.—Iwanow says that only 8 cases of **vaginal extirpation of the uterus** during delivery have been reported, 2 by Winter and 1 each by Chrobak, Neugebauer, Solowij, and Mertens and 2 by himself. This does not include those in which the uterus was removed by vaginal cesarean section for uterine cancer. Iwanow's first case was reported in the *Centralblatt*, No. 2, 1899. His second case, now reported, also had a favorable result, and confirms his preference for the vaginal method. The ease and rapidity of the operation, known to all who have used it, are its best recommendation. Another advantage is, there is much less danger of infection of the patient. He also lays much weight upon the drainage of the abdominal cavity through the vagina. [W.K.]

Original Articles.

MILITARY SURGERY.

By W. C. BORDEN ("EDRO"), M.D.*

Captain Medical Department U. S. Army; Professor of Surgical Pathology and Military Surgery, Georgetown University, Washington, D. C.

(Concluded from page 303.)

Wounds of the Face.—Wounds of this region gave a mortality of 5.8%, the lowest regional mortality in the Civil War; while in the Spanish-American War they gave a mortality of 6.7%, being more fatal even than in the Civil War and much more fatal than wounds of the extremities (Table V). This grave nature of wounds of the face is rather surprising, and seems to indicate that wounds of this region by the small-caliber bullet are not so benign as might be expected from the apparent immunity with which the face is pierced in some instances, of which the case in Figure 3 is an example. The septic condition of the nasal cavities and mouth, and the proximity of the brain are the factors of danger in these cases, for of the 4 deaths which resulted from wounds of this region in the Spanish-American War, 2 were from septicemia and 2 from meningitis.

Wounds of the Neck.—Wounds of this region are probably frequently immediately fatal from injury to the great vessels, and wounds of important nerves and structures may add to the gravity of the traumatism even when death is not immediate. This is shown by the fact that in the 35 reported cases in the Spanish-American War, there were 7 deaths, a mortality of 20% (4), while in the Civil War, wounds of the same region gave a mortality of 15%. Thus in this region as with the head, statistics show a mortality at variance with the impression made by seeing numerous cases of bullet perforations of the neck with apparently little bad effect. As no wounds of the spine are recorded in this class and as flesh wounds by the small-caliber bullet are notoriously aseptic, the bad results must be entirely due to severe traumatisms of important structures in the neck; and, as the mortality reported is high, even though the total number recorded is small, it may be concluded that *the use of the small-caliber rifle has not decreased the mortality in wounds of the neck.*

Wounds of the Spine.—Wounds of this region are rare, forming but one-fourth to one-half percent of all cases (Table V). They are, however, extremely fatal, as they give the highest percentage of mortality of the wounded of any class of wounds.

Civil War.....	55.5
Franco-Prussian War (Germans)	67.7
Spanish-American War (U. S. Reg).....	62.5

The causes of death in gunshot wounds of the spine are: (a) direct injury to the cord by the missile; (b) hemorrhage from severance of spinal bloodvessels; (c) spinal meningitis; (d) myelitis or degeneration; (e) degeneration of the kidneys and cystitis from trophic lesions of the urinary organs; (f) exhaustion from bedsores. When the spinal substance is injured the mortality is always very high, as Otis states that the spinal injuries during the Civil War followed by recovery were

exclusively those in which the osseous structure of the spine only was involved. Like the traumatic effect upon the brain, traumatism of the spine by the small-caliber bullet are of a very serious character. Dent, in speaking of this class of injuries in the Anglo-Boer War, says that no cases in hospital seem more hopeless or more distressing.¹⁷ He remarks upon the astonishing rapidity of the degenerative changes which occur—deep sloughing bedsores forming in a day or two and cystitis setting in early. He says that if there is any grave lesion of the cord the wound may be set down as mortal even when the wound affects but a small portion of the cord. Even when the traumatism is small, the bullet possibly having barely grazed the cord, the area of damage may be very great. This extensive injury to the cord is undoubtedly due to the fact that it is fluid-saturated, and therefore, like other similarly saturated organs, transmits the energy of a high-velocity missile with lateral explosive violence. It also appear (Table V) that a larger percentage of injuries of the spine will occur from the use of the new rifle—the percentage of occurrences in the Spanish-American War being double that of the Civil War (0.26 to 0.54). This is to be expected; for, from the greater penetrating power of the new bullet, a protected part like the spine is more liable to be reached.

From this it appears that the use of the small-caliber rifle has certainly not decreased the gravity and has increased the frequency of wounds of this class. The number of wounds of the spine in the Spanish-American War was small. There were but eight such wounds reported, but of this number five died. While this number is hardly sufficient for more than very general statistical conclusions, it certainly points to the extreme fatality of this class of wounds and appears to demonstrate that notwithstanding the resources of modern surgery, the destructive effect of the small-caliber bullet upon the spine is so great as to make the percentage of recovery in this class of wounds extremely low. The conclusion reached, therefore, is that *use of the small-caliber bullet has not diminished the gravity of wounds of the spine, and has increased the mortality of the wounded by increasing the number of wounds of this class.*

The treatment of gunshot wounds of the spine should be carried out only under the strictest aseptic precautions. If suppuration occurs it certainly leads to fatal spinal meningitis and myelitis. Operative treatment, therefore, can be recommended in these cases only where aseptic technic can be employed. This is rarely the case in the field hospitals, but at base and general hospitals where means are available, operative measures should be instituted in all appropriate cases. Under such conditions formal or informal laminectomy should be done, and all bone-splinters and depressed bone removed in order to relieve the cord from pressure or irritation.

The complications arising in these cases, such as cystitis and bedsores, should be treated on the general principles of surgery, and every possible means should be used to prevent their occurrence.

Wounds of the Chest.—Wounds of the chest furnish about 8% of all wounds received in war, ranking next to wounds of the extremities in order of frequency (Table V). Wounds of this region probably furnish a large proportion of immediately fatal results from injury to the heart or great vessels, as in 64 deaths in the Spanish-American War, the causes of which were reported. 17 were due to penetrating wounds of the chest.

* The paper signed "Edro" was awarded the Sander prize (a gold medal) for the best paper on military surgery, submitted for competition at the annual meeting of the Association of Military Surgeons of the United States, held in New York City, May 31 to June 2, 1900. The committee of award consisted of Brig.-Gen. J. D. Griffith, Surg.-Gen. N. G. Mo.; Medical Director Geo. W. Woods, U. S. Navy; and Major A. C. Girard, Surgeon U. S. Army, and all papers were submitted to the committee with their *nominations de plume* only.

Wounds of this region are divided into nonpenetrating and penetrating, according to whether the chest-wall only is involved or whether the pleural cavity has been entered with or without injury to the chest-contents. This division is a most important one from a standpoint of prognosis; for while the mortality in penetrating wounds is very high, but few nonpenetrating wounds prove fatal, even though the ribs may be involved, and are generally dangerous only when the destruction of tissue is extensive—as is sometimes the case with shell-wounds—or from extension of infection to the pleura when the wound is infected. With the resources of modern antisepsis these dangers are mainly done away with, and nonpenetrating wounds of the chest will probably sink into insignificance as mortality-producing factors. In the American Civil War, 3.2% (Otis) of all such cases were fatal, while in 61 such cases occurring in the Spanish-American War, there were no deaths.

Penetrating wounds of the chest are much graver injuries.

TABLE VII.—SHOWING PERCENTAGE OF MORTALITY IN PENETRATING WOUNDS OF THE CHEST.

		PERCENT.
French in Crimea	(Chenu.)	91.6
English in Crimea	(Matthew.)	79.2
French in Italy	(Chenu.)	46.48
Civil War	(Otis.)	62.66
Prussian in Schleswig 1864	(Lotter.)	41.6
Danish in Schleswig	(Lotter.)	67.2
Germans in Franco-Prussian War	(Fischer.)	56.7
Japanese in Chinese War (16 cases)	(Haga.)	34.7
Spanish-American War (American regulars)	(Official.)	24.5

In the Spanish-American War, 58 cases of penetrating wounds of the chest were reported, with 13 deaths (24.5%). By this it will be seen that the mortality in this class of cases is distinctly lower than in former wars when a large bullet was used (Table VII.) All observers have remarked upon the immunity with which in many cases the chest is penetrated or perforated by the small-caliber bullet. This was remarked upon by Senn at Santiago and by Treves in South Africa, who state that there were often no symptoms in these cases beyond an immediate hemoptysis, which was not repeated. The lower mortality in recent wars is probably mainly due to the character of the wounds made by the small-caliber bullet. From the aseptic nature of these wounds, infection, when it occurs, is probably usually due to infection from the lung rather than from the external wound. Notwithstanding the favorable course of many cases, it should be noted that wounds of the chest are of grave import and should by no means be treated lightly. This is shown by the fact that in the Spanish-American War, practically one-fourth of those wounded died. Greenleaf has called attention to the gravity of these cases, and has shown that serious complications are by no means uncommon.¹ In 24 cases of gunshot wounds of the chest which he collected from the Spanish-American War records, 9, or 37%, developed complications; 3 had hemothorax, and 6 developed hemothorax which became purulent and required operation. From these cases he argues that gunshot wounds of the chest by the small-caliber bullet are not of as light a nature as was supposed and that care should be taken in treat-

ing them. Treves, in speaking of similar wounds in the Anglo-Boer War, says that he has seen surgical emphysema, hemothorax, pneumothorax, and an example or two of empyema, but that, on the whole, gunshot wounds of the chest do well.

Aside from lowered mortality due to the small-caliber bullet, the *treatment* adopted has undoubtedly had much to do with reducing the number of deaths in these cases. It should be directed: (a) to immediate care of the wound; (b) to the complications which may arise.

The primary use of protective dressings will often prevent subsequent infection of the wound, or pleura, with possibly resulting empyema. The serious complications which may follow are: (a) hemorrhage; (b) hemothorax; (c) pneumothorax; (d) empyema; (e) pleurisy or pneumonia; (f) abscess of the lung.

Hemorrhage is of course to be treated by ligation, or pressure by Dessault's plan when the ligation is impracticable. Hemothorax being the result of hemorrhage, the bleeding should, if possible, be controlled by ligation; or if it occurs from the lungs, sedatives, cold applications, and absolute rest should be tried. These failing and the case being urgent the clots should be turned out and ice-water should be injected into the pleural cavity as recommended by Delorme. Where the bleeding has stopped and operation is required, tapping and evacuation by syphonage, as recommended by Senn, should be employed.

Empyema should be treated by free drainage, daily irrigation with warm antiseptic solution and final resort to Estlander's operation if necessary. Abscesses of the lung should be evacuated and treated on similar lines. The surgery of the lungs and pleura has made great advances of late years and adoption of the methods now in vogue will do much to lessen the mortality in complications arising from gunshot and other traumatism involving the pleural cavity or the thoracic contents.

From this and the statistics available, it may be stated that the use of the small-caliber rifle has lowered the mortality in penetrating wounds of the chest and that modern surgical methods have also been a decided factor in this direction.

WOUNDS OF THE ABDOMEN.—Wounds of the abdomen, like those of the chest, are divided into nonpenetrating and penetrating. *Nonpenetrating* wounds of this region, like similar ones of the chest, are of minor importance.

Penetrating Wounds of the Abdomen.—These wounds cause a large proportion of immediate deaths on the field of battle.

In 64 deaths from gunshot in action in the Spanish-American War, in which the cause of death was reported, 19 were due to wounds of the abdomen. These immediate deaths were undoubtedly due: (a) to hemorrhage from wound of some bloodvessel; (b) to hemorrhage and shock from wound of some one of the large intra-abdominal organs. These organs—liver, spleen, kidneys—are blood-saturated organs, and at short range the compound bullet often acts upon them with destructive violence. Also, the stomach or bladder, if filled with fluid, may be extensively torn or ruptured. This is due to the violent transmission of energy in all directions from the rapidly moving bullet by the incompressible fluid in fluid-filled or fluid-saturated organs, as was pointed out in the discussion of explosive effect. In these cases extensive laceration and disruption of the organs occur with consequent hemorrhage and shock, which immediately or quickly cause death.

At long range and lower velocities the bullet may simply perforate these organs and recovery take place with few symptoms. Numerous cases of this kind have been reported by surgeons in both the Spanish-American and Anglo-Boer wars, and have been as much commented upon as have similar wounds of the skull or brain.

No class of cases, however, have been so tremendously fatal in war as penetrating wounds of the abdomen, and they still show the highest mortality of wounds of any region. (Table VIII.)

TABLE VIII.—MORTALITY FROM PENETRATING WOUNDS OF THE ABDOMEN.

	NUMBER.	DIED.	MORTALITY.
Crimean War—English	120	111	92.5
Crimean War—French	121	111	91.7
Italian War—French	246	163	87.2
Civil War—Federals	3,717	3,031	87.2
Danish War—Prussians	103	59	57.2
Danish War—Danes	89	57	64
Franco-Prussian War (Fischer)	1,047	784	74.8
Japan-China War (Haga)	47	33	70.2
Spanish-American War (U. S. Regulars)	41	29	65.0
Average mortality			74.3

These figures show an average mortality, previous to the Spanish-American War, of practically 75%. This seems to indicate that the mortality in these cases has been somewhat lowered by the use of the new rifle. The gain would be more evident if it were not for the figures of the Italian War and the Danish War, in both of which, though large-caliber bullets were used, the mortality was lower than in the Spanish-American War. Taking the other wars into account, there is a decided improvement in the mortality—the decrease as compared with our Civil War being over 20%.

In considering the statistics of the Spanish-American war, the factor of treatment should be taken into account.

Penetrating wounds of the abdomen (U. S. Regulars), 44. Laparotomies for these wounds, 4; deaths, 4; mortality, 100%.

Cases not operated on, 40; deaths, 25; mortality, 62.5%.

The statistics from the Spanish-American War for these cases are small, and it may be that the larger figures which we shall have from the Anglo-Boer War will still further emphasize the comparatively humane effect of the small-caliber bullet and the good results of conservatism in penetrating gunshot of the abdomen. The large percentage of deaths in these cases is due to septic peritonitis, but with the small bullet there is less danger of infection either from the exterior or from fecal extravasation than with the large bullet. From the usually aseptic nature of the wounds made by the small bullet, it may be presumed that peritoneal infection only exceptionally occurs by way of the surface of the body. Infection, when it does occur, must therefore usually be due to extravasation from wounds of the intestinal canal. Undoubtedly there are a number of cases in which intestinal perforation occurs and peritonitis does not result, for both Treves and McCormick report such cases among the British wounded in South Africa. McCormick suggests that it is due to an empty alimentary tract

and the rapid closing of the small perforation made by the bullet, and Treves suggests that the small hole may be closed by apposition with an adjacent coil of intestine. In an empty intestine or stomach, the small-caliber bullet probably produces as small a hole as it does in other soft tissues, and the contraction of the tissues tends to close the small opening, while adhesion to an adjacent intestine may readily occur. Also, a certain number of penetrating wounds occur in which the intestines or intraabdominal organs are not injured. These conditions all aid to lessen the gravity and mortality of wounds of this region.

To summarize, it may be concluded that modern surgical methods have not as yet proved available to markedly reduce the mortality of the wounded in penetrating wounds of the abdomen received in war; but, that the mortality in these cases has been lowered to some extent by the use of the small-caliber rifle.

Wounds of the pelvis and genitourinary organs taken together, in the Civil War had the high mortality of 29.7%. In the Spanish-American War no cases of wounds of the pelvis were reported, but there were seven wounds of the perineum and genitourinary organs with no deaths. Wounds of the pelvis depend largely for their gravity upon whether or not the pelvic contents are injured. If the pelvic peritoneum is involved the wounds belong to the same class as penetrating wounds of the abdomen and the mortality from them and the treatment indicated are practically similar.

Wounds of the pelvis proper by the small-caliber bullet will not be as grave as in former wars. The osseous structure of the pelvis is spongy and will not be as greatly shattered by the small-caliber bullet as by the larger bullet formerly used, while the aseptic nature of the wounds made by the new bullet and the antiseptic treatment now adopted for lacerated and infected wounds made by other missiles will tend greatly to lower the mortality in cases where the extraperitoneal structures only are involved.

Wounds of the bladder are dangerous from the extravasation of urine into the tissues, or its escape into the peritoneum if that cavity is wounded. With the new bullet it is possible that the bladder may be pierced and no bad results follow, but in some cases active treatment will be required. Operative treatment at the field hospital is not to be recommended except in extremely urgent cases, and especially not if the peritoneum is involved. If the peritoneum is opened by operation the chances for recovery will be as infinitesimal as in laparotomy for abdominal penetrations. Operations, not involving the peritoneum, may be attempted where immediate interference is necessary, but all cases in which delay is possible should be transported to base hospitals where proper technic is available. When required, a catheter should be introduced and retained in the bladder, and other palliative treatment adopted until operation can be done with safety.

WOUNDS OF THE EXTREMITIES.

It is in the wounds of these regions that the use of the small-caliber rifle and modern surgical methods have produced the great saving of life and limb. Wounds of other regions of the body, as already shown, present but a moderate reduction in fatality. But wounds of the upper and lower extremities have been surprisingly less fatal in wars where the small-caliber bullet has been used and where the wounds have been treated by aseptic and antiseptic means and by the ex-

pectant and conservative treatment which is a natural concomitant of these methods. (Table IX.)

TABLE IX.—NUMBER OF CASES AND MORTALITY FROM GUNSHOT OF THE EXTREMITIES IN THE CIVIL WAR AND SPANISH-AMERICAN WAR (U. S. REGULARS).

		CASES.	DIED.	MORTALITY.
Civil War	Upper extremities.	87,793	5,608	6.5
Spanish-American War	Upper extremities.	429	1	0.2
Civil War	Lower extremities.	73,665	11,813	13.8
Spanish-American War	Lower extremities.	562	9	1.6

Thus in the Civil War, while the mortality of all wounds of the extremities, upper and lower, was from 6.5% to 13.8%, similar wounds in the Spanish-American War had a total mortality of but 2.4%. The number of deaths in the latter war from wounds of these regions is surprisingly small, but 10 in 991 cases; and of these 10 cases, 3 died very shortly after the receipt of their injuries, probably from hemorrhage.⁴ The difference in treatment adopted in these wars is not less great than the mortality. (Table X.)

TABLE X.—WOUNDS OF THE EXTREMITIES TREATED BY EXCISION AND AMPUTATION, AND BY CONSERVATISM, AND THE RELATIVE MORTALITY OF EACH TREATMENT FOR TWO WARS.

WAR.	WOUNDS OF EXTREMITIES.		AMPUTATIONS AND EXCISIONS.		PERCENT. AGE OF OPERATIONS TO WOUNDS.	OPERATIVE MORTALITY.	CONSERVATIVE MORTALITY.
	Total.	Deaths.	Total.	Deaths.			
Civil	174,206	17,421	12,193	2,636	6.99	21.4	9.1
Spanish-American	991	10	32	6	3.20	18.7	0.4

This table shows at once: (a) The small number of operations done or required to be done in wounds of the extremities since the adoption of the new rifle and modern surgical methods—the proportion having been *reduced over one-half* (6.99 to 3.20); (b) the great decrease in mortality in these cases, the mortality being *reduced over twenty-two times* in cases treated conservatively (9.1 to 0.4), and somewhat decreased in those treated by amputation or excision.

The high mortality in operation cases makes it probable that only the extremely serious cases were operated on. In the Spanish-American War in the cases reported among the regulars, the deaths that occurred were all from high amputations. (Table XI.)

TABLE XI.—RESECTIONS AND AMPUTATIONS AND DEATHS FROM THESE OPERATIONS IN THE SPANISH-AMERICAN WAR (REGULAR TROOPS).

	RESECTIONS.	AMPUTATIONS.	DEATHS.
Arm	1	4	1
Forearm	1	2	0
In hand	0	13	0
Hip joint	0	2	2
Thigh	1	5	2
Knee	0	1	1
Leg	0	1	0
Ankle	0	1	0
Total	3	29	6

No deaths from resection.

From this it may be formulated that the use of the *small-caliber rifle and modern surgical methods have together greatly reduced the loss of life and limb in gunshot wounds of the extremities.*

Having considered wounds of the extremities in general, it remains to study wounds of the joints and bones, wounds of the soft parts having been sufficiently discussed under the general heading of wounds.

Wounds of the Joints.—In no department of military surgery has the treatment of wounds been so greatly changed and for the better as in gunshot wounds involving the joints. From radical operative interference usually by amputation above the wounded joint, treatment has changed to expectant and conservative lines, and with a result in saving of life and limb which is truly astonishing. The credit for inaugurating this change is due to von Bergmann, whose brilliant results in the Russian-Turkish War with wounds of the knee-joint treated by occlusive and antiseptic dressings and immobilization, inaugurated a new era in the military surgical treatment of joint wounds.²²

In the battle of Gorne Dubrik, von Bergmann selected 15 of the most serious cases of gunshot of the knee in which, aside from the implication of the joint, there was extensive comminution of the bone. In these cases treated by the above method, perfect recovery resulted, with but a single exception, notwithstanding the fact that the patients were exposed for days to pouring rain and had to be transported across the plains over muddy roads. In the same war, of other cases treated by the older methods then in vogue, 95% died.

In considering von Bergmann's brilliant results, it must be borne in mind that the wounds treated were made by the large lead bullet then used, and that the results must be attributed to the treatment rather than to any effect of the missile.

The same line of treatment was adopted by Haga³ in the Japan-China War and by our surgeons in the Spanish-American War. The excellent results obtained as well as the comparatively tremendous mortality in previous wars is shown in Table XII. In this connection, Table XIII is also very valuable and interesting as it shows that the deaths from joint-injuries in two wars since the adoption of aseptic and antiseptic methods and expectant treatment have all been from wounds of the larger joints.

The four deaths reported by Haga were from wounds of the hip and knee, and the *single death from joint-wound in the Spanish-American War among the United States Regulars was due to a gunshot of the knee treated by amputation.*

TABLE XII.—MORTALITY OF WOUNDS OF THE JOINTS IN FOUR WARS.

JOINT.	AMERICAN CIVIL WAR.	FRANCO-PRUSSIAN.	JAPAN-CHINA (Haga).	SPANISH-AMERICAN (Regulars).
Hip	84.7	71.8	100.0	0.00
Knee	73.7	48.9	25.0	5.5
Ankle	26.9	24.0	0.0	0.0
Shoulder	31.1	35.5	0.0	0.0
Elbow	19.4	21.2	0.0	0.0
Wrist	12.9	12.6	0.0	0.0

TABLE XIII.—CASES AND DEATHS IN EACH CLASS OF JOINT-WOUNDS IN TWO RECENT WARS.

	JAPAN-CHINA WAR. (Haga).		SPANISH-AMERICAN WAR. (Regulars).	
	Number.	Deaths.	Number.	Deaths.
Hip	1	1	0	0
Knee	16	4	18	1
Ankle	4	0	11	0
Shoulder	4	0	3	0
Elbow	16	0	5	0
Wrist	6	0	6	0
Total	47	5	43	1
Mortality	10.6%		2.3%	

Operation was done in but 2 of the 43 Spanish-American War cases. These were both amputations, one for gunshot of the ankle-joint and one of the thigh for gunshot of the knee-joint, the latter amputation as just noted giving the only fatal result which followed gunshot of the joints in the regular troops during the Spanish-American War.

In the Civil War, gunshot of the knee-joint, next to wounds of the skull, brain, spinal cord, and abdomen, gave the highest mortality of any class of wounds—approximately one-half of those wounded died—while in the 38 cases of Table XIII, there are but 5 deaths, or less than 1 death in 7, and in the American cases there is but 1 death in 18 cases and that followed operation. No stronger argument could be adduced for conservatism in *bullet* wounds of the joints. The conditions are practically identical with those present in penetrating abdominal wounds, for in each there is the probability of an aseptic wound which may be made septic by operation, especially if the operation is attempted at the field hospital. The rule of conservatism should be as firmly adhered to in one case as in the other. In civil practice, with all the technic of asepsis, the surgeon may when necessary open a joint as fearlessly as he would the abdomen; but in military practice, in view of the high mortality from operation and the almost certainty of cure by conservatism, the military surgeon should open joints or amputate only when the life of the patient is in imminent peril. The surgeon will be aided along conservative lines by the fact that the small-caliber bullet, except at very short range, rarely fragments the articular ends of bones to marked extent. The bullet in many cases may pass through joints and simply perforate or but slightly fissure the bones. Considering this in its relation to conservative treatment it should be remembered that septic infection more frequently produces ankylosis and impaired function of a joint than does bone-displacement, unless the displacement is marked; and that septic infection of a large joint is a great menace to life.

But in some cases operative interference will be demanded. This necessity will most ordinarily arise from extensive traumatism, from shells or deformed ricochet bullets, or from infection of the wounds. In such cases the operation which will best serve will have to be determined for each individual case, taking into consideration that in a choice between excision and amputation some general rules have been found to best apply for wounds of certain parts. Thus, in general terms, it may

be stated that where bone and tissue destruction is not too great, military surgical experience has shown that excision is to be preferred to amputation in all joints except the knee and ankle. With aseptic and antiseptic technic available, it is possible that more excellent results may be obtained in excision of these joints in the future than has been had in the past, but as yet a sufficient number of cases are not recorded from which to draw conclusions.

In summarizing conclusions relative to joint-wounds it may be stated that *the mortality in joint-wounds has been remarkably diminished by the adoption of aseptic, antiseptic, and conservative methods and by the use of the small-caliber rifle.*

Gunshot Fractures of the Extremities—The effect of the small-caliber bullet upon the long bones has already been discussed; it remains to study the treatment of these traumatisms. It may be said at once that the treatment adopted in compound fracture by gunshot has as radically changed, and that for the better, as has the treatment of gunshot of the joints. (Table XIV.)

TABLE XIV.—COMPARATIVE MORTALITY OF COMPOUND FRACTURES IN THE CIVIL AND SPANISH-AMERICAN WARS ACCORDING TO TREATMENT ADOPTED.

	MORTALITY, CIVIL WAR.		MORTALITY, SPANISH-AMERICAN WAR.	
	Treated Conservatively.	Treated by Amputation or Excision.	Treated Conservatively.	Treated by Amputation or Excision.
Arm.	14.3	26.0	0.0	20.00*
Forearm.	6.4	13.9	0.0	0.0
Thigh.	49.19	62.4	0.0	57.1*
Leg.	13.8	50.5	0.0	0.0

* One operation only.

From this table it will be seen that as with the joint-wounds, conservatism is made possible in gunshot fractures by the aseptic nature of the wounds made by the small-caliber bullet and that, aided by aseptic methods, conservatism has reduced the mortality in these cases to an extent almost beyond belief. The gravity of compound fractures depends mainly upon the presence or absence of infection, and where this can be excluded or prevented, traumatism of the bones heal as well as traumatism of other tissues. In the Spanish-American War 100 gunshot fractures of the extremities, exclusive of the foot and hand, were reported among the U. S. Regulars. In these 100 cases there were but 5 deaths and these only in cases operated on. (Table XV.)

TABLE XV.—CASES, OPERATIONS AND DEATHS FROM COMPOUND FRACTURES OF EXTREMITIES; U. S. REGULARS, SPANISH-AMERICAN WAR.

	CASE.	DIED.	RESECTIONS.	AMPUTATIONS.	DEATHS FROM AMPUTATIONS.
Arm.	18	1	1	4	1
Forearm.	26	0	1	2	0
Thigh.	30	4	1	6	4
Leg.	26	0	0	1	0
Total.	100	5	3	13	5

Mortality in all cases 5.4
 Operative mortality 81.2%
 Conservative treatment mortality 0.0.

It is to be noticed that the deaths all occurred after high amputations, 2 being amputations at the hip-joint of which both died; 2 amputations in the middle third of the thigh with 1 death; and 2 amputations in the lower third with 1 death. The death from amputation of the arm was in a case operated on at a dressing station, death occurring 18 days later, probably the result of infection due to operation in septic surroundings. The results tabulated in the tables given show most emphatically that conservation should be practised in all cases possible.

When *operative measures* have to be adopted the question of excision or amputation will arise.

Excision in the shaft of the long bones has been unfavorably considered by military surgeons in the past. The mortality from this operation has been greater than that from amputation, and the functional use of the part has, as a rule, not been good. It is to be noted, however, that the large statistics now available are from wars in which aseptic and antiseptic methods were unknown and that in recent wars operations have been too few to warrant conclusions. It would seem that with the resources of antiseptis and asepsis that limbs could be saved in many cases by recourse to excision and without greater danger than is entailed by amputation.

The reduced though still high mortality from amputations shown by Table XV, like the high mortality from amputation for joint-wounds, is undoubtedly due to these operations being done only on the worst cases. Amputations and excisions will of course still be necessary in gunshot fractures when destruction of the soft parts is great, when the main vessels of the part are severed and when infection, if present, cannot be controlled. The rule, however, is conservatism in these cases; the results from this line of treatment and the decreased mortality in gunshot of the bones of the extremities being such that it may be formulated: *the use of the small-caliber rifle and modern surgical methods have, together, greatly reduced the mortality in gunshot fracture of the extremities.*

General Conclusions.—In reviewing the foregoing it may be safely stated that the facts and figures show that the military weapon now used in war which inflicts the great majority of wounds, *i. e.*, the small-caliber rifle, together with the surgical methods now in vogue have materially affected the practice of military surgery. Operative measures once thought imperative are now no longer required. The aseptic character of the wounds made by the small-caliber bullet allows conservatism in many cases where radical measures were formerly necessary, while the traumatism produced by it in many cases and in certain regions of the body, is directly conducive to a minimum of evil result. At the same time the effect of the bullet in other regions is such that the mortality of the wounded has not been greatly diminished.

Relative to the use of the small-caliber rifle it may be stated:

1. That the small-caliber rifle is *not* a humane weapon so far as its immediate death-dealing power is concerned.

This is proved by the statistics which show that the proportion of killed to wounded has, if anything, been increased by its use.

2. That it is a humane weapon so far as the effects of its projectile upon those not immediately killed are concerned.

This is shown by the statistics, which demonstrate that many more wounded recover and more limbs are saved, than when rifles of large caliber were used.

3. That in certain regions—head, face, and neck—it produces injuries of such grave character that modern surgical methods have not been able to reduce the mortality in wounds of these parts.

This is shown by the fact of the still high mortality of wounds in these regions, although treated according to the surgical principles which now obtain.

4. That in wounds of other regions: chest, abdomen, and pelvis, the wounds as a class are less dangerous than with the old bullet, but in all these regions, the chest not excepted, are usually of grave import.

This is shown by the high mortality which still obtains in this class of wounds.

5. That in wounds of the extremities, the small-caliber bullet produces wounds which are rarely mortal, and which allow conservative treatment to an extent heretofore unknown. *It is in wounds of the extremities that the great reduction in mortality has occurred since the adoption of the new rifle and the use of aseptic and antiseptic methods.* This is proven by the tremendous reduction in mortality in wounds of these regions and the reduced number of major operative measures required.

Relative to Surgical Methods: 1. That asepsis and antiseptis have been as potent factors in reducing post-traumatic complications and mortality in military as in civil surgery.

This is proven by the reduced mortality arrived at by *recognizing and maintaining* the asepticity of bullet-wounds, and by treating infected wounds antiseptically, and, when necessary, by aseptic and antiseptic operative procedures.

2. That conservative treatment, made possible by aseptic and antiseptic methods, has been a most potent factor in the saving of life and limb.

This is proven by statistics of wounds of joints and compound fractures where the mortality from cases so treated is almost infinitesimal.

3. That operative interferences on the field or at field hospitals should be restricted to operations imperatively demanded or to those cases where delay would be more dangerous than the septic infection liable to occur from operating under unfavorable conditions.

This is proved by the high mortality and the post-operative infection in cases operated on at the front—due to the practical impossibility of obtaining asepsis under the conditions which obtain at field hospitals.

Relative to Executive Departments: 1. That permanent base, and general hospitals equipped with all appliances for aseptic and antiseptic work should be established at points as accessible as possible to the field of operations and that facilities for transporting the wounded to these hospitals as quickly as possible should be provided.

By having hospitals so equipped and sending the wounded directly to them, lodged bullets can be located by the Röntgen-ray and removed with safety; operations for compound fractures where there is irreducible displacement of bone, or where the Röntgen-ray shows displacement liable to produce impairment of function, can be done and other necessary operative procedures can be safely undertaken with resulting conservation of function, limb, and life. This was the method adopted in our war with Spain and in the Anglo-Boer War; and, if carried out in future wars, will greatly aid to reduce post-traumatic complications and the mortality of the wounded.

Finally, it is to be remarked that military surgery, viewed as a science, does not differ from surgery in general. It is governed by the same laws and founded on

the same principles. Viewed as an art, it differs from ordinary surgical practice in that it deals with traumatism seldom met with except in the field of war, and that being practised under peculiar and less favorable circumstances is less certain in its effect. Locality and environment frequently make a more heroic and decided form of treatment necessary; and equally, at other times demand that more conservatism be practised than in ordinary surgery. And lastly, military surgery demands of the military surgeon, not only that he should be well informed of the peculiar class of cases with which he has to deal and of the conditions under which they must be treated, but that he should be well grounded in the science of surgery in general, so that with comprehensive grasp and ever holding in view the ultimate welfare of his patient, he may bend his energies to that great end and apply his knowledge according to time, place, and circumstances with rightful prospect of success.

AN APPARATUS FOR MAKING ROLL-CULTURES.

By GEORGE H. F. NUTTALL, M.D., PH.D.

University Lecturer in Bacteriology and Preventive Medicine, Cambridge, England.

THE roll-culture method, which was introduced by von Esmarch, is still used to a considerable extent in certain laboratories. In making rolls according to the original method, the cotton plugs (of the tubes containing the liquefied gelatin) are cut off on a level with the mouth of the tubes, and covered by rubber caps. The tubes are then rolled in cold water by hand or by means of the apparatus devised either by von Esmarch or Prausnitz. The drawback to this method is that it is difficult to spread the gelatin or agar in a uniform layer within the tube, and it is almost impossible to avoid

sary when the tubes are rolled on ice, as first suggested by Booker, of Baltimore. He used ordinary test-tubes, rotating them upon a block of ice into which a groove of suitable size had previously been melted by means of a tube containing hot water. With a very little practice, excellent roll-cultures of gelatin or agar can be

FIG. 2.—(a) Represents dripping water.

made by Booker's method. By tilting the piece of ice, which rests upon a towel, within a basin, there is no difficulty in keeping the medium from coming in contact with the plug. The Booker method requires that one shall have a piece of ice of suitable size at hand. The continued melting of the ice alters the shape of the groove, so that a new one must, after a short time, be melted in the ice. Ice is an expensive item if this method is much used, whereas the Booker method will always be useful where ice is readily obtained. I believe a useful substitute for the ice-block will be found in the simple apparatus about to be described. The apparatus is always at hand, and the cold water, as it runs from the tap, suffices during the greater part of the year for chilling the tubes. In summer, ice-water can be allowed to run upon the tubes from a reservoir overhead. In this apparatus the form of the groove remains constant.

The apparatus consists of two parts: (1) A block of marble; (2) a metal receptacle with attachments. The block (21 x 17 x 5 cm.) is provided upon its upper polished surface with two grooves (b), of a size adapted to tubes of different sizes (the one groove is 17, the other 13.5 cm. long). In cross-section, the grooves must represent somewhat less than a half circle, otherwise the water which accumulates between the surfaces of the tube and groove exerts such an amount of capillary attraction as to seriously interfere with the rotation of the tube. On the right-hand side of the block, about 1 cm. from its edge, is a single groove, deeper than the preceding, which it traverses. This groove serves to drain off the water, which would otherwise run along the length of the tube and wet the plug. Owing to the capillary attraction before-mentioned, the tubes will not rotate properly within a polished marble groove. They, however, rotate very rapidly when the surface of the groove is covered with a thin coat of paraffin, which is melted, applied by means of a brush and smoothed with a heated glass tube. The layer of paraffin requires to be occasionally renewed, the dried block being previously wiped off with a cloth moistened with xylol or turpentine. As seen in the figure, the block is held in a slanting position within the receptacle, which is made somewhat larger than the block, so as to catch any water which may flow over its sides. The

FIG. 1.—(c) Represents dripping water.

bringing the medium in contact with the plug. When the medium collects about the plug the number of colonies developing within the tube cannot be accurately determined. To obviate this difficulty, special tubes with narrowed necks have been resorted to. Such tubes, as also rubber caps, are, however, quite unneces-

shape of the receptacle is adapted to that of the block, the front and left side being high, so as to catch the water as it splashes from the rotating tube. At the back is attached a vertical rod with a screw attachment to hold a perforated brass T-tube (*d*), through the four openings of which water is allowed to fall upon the tubes. The floor of the receptacle is flat. On the left side is a tube, to which a piece of rubber tubing is attached, the same serving to drain off the water which flows into the receptacle. The receptacle rests upon two sleigh-like cutters, which are cut away somewhat at the left side, so that by pressing down upon the left handle (*c*) of the receptacle it is possible to give the whole apparatus a decided tilt to one side. As soon as this handle is released, the apparatus returns by its own weight to the horizontal position. On the right of the receptacle is a second handle, which, together with the first, serves for carrying the apparatus about. These handles should be made sufficiently wide to admit the four fingers of each hand.

When the apparatus is to be used, water is allowed to flow with *moderate* rapidity from the spray, the left handle is pressed down, and the culture-tube placed in the groove, rotation beginning immediately. As soon as the tube is rotating properly, the apparatus is allowed to gradually resume the horizontal position, and the rotation is continued until the medium has solidified. Solidification occurs rapidly with agar, more slowly with gelatin; so that when the latter is used it will save labor (when the water is not especially cold) to bring down its temperature to near the point of solidification before placing it in the apparatus. It is already known that it is necessary to keep agar-rolls in a slanting position for the first 24 hours in the thermostat. This allows the film of agar near the plug to become dried and attached to the inner surface of the tube; whereas if the tubes are placed in a vertical position immediately after rolling, the agar film slips down within the tube, after the manner of a loose stocking. The dried agar at the edge serves, so to speak, as a "garter." The tubes should be rotated only in one direction (towards the operator), using the tips of one or two fingers gently. Splashing can be considerably reduced by moving the finger backward and forward *between* the small water-jets. By placing the apparatus in a slanting position, it can also be used for slanting media. Any stonemason can make the block required—a workman here has made them for 8 shillings, while a tinsmith makes the receptacles of zinc for about the same price. The marble block has the advantage of giving the apparatus stability. Herr Paul Altmann, Luisenstrasse, 52, Berlin, N. W., will supply a thoroughly well-made apparatus complete for 25 marks.

MÜTTER LECTURES OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

The Surgical Treatment of Congenital and Pathologic Disfigurements of the Face.

By JOHN B. ROBERTS, M.D.

Professor of Surgery in the Philadelphia Polyclinic.

LECTURE X.—*The Cosmetic Surgery of the Eyes.*

(Abstract.)

MUCH can be done for improving disfiguring conditions of the eyeball and eyelids. One of the most

common of the ocular conditions causing an unseemly expression of the countenance is strabismus. The internal form is usually associated with hyperopia and requires proper correction of the refractive condition, in addition to section of the internal rectus muscle. Failure to wear lenses to correct the refractive defect causes not infrequently a return of the cross-eye condition. I have now under my care a patient in which the strabismus returned, apparently from neglect of this precaution on the part of the former operator. The various operations for correcting internal and external squint, or strabismus, by cutting the muscles, advancing the tendons, or by a combination of both operations, need not be discussed in detail; they are familiar to all ophthalmic surgeons.

Disfiguring white spots upon the cornea may be tinted with India ink. This little operation must be frequently repeated in order to get the tint of the scar-tissue sufficiently dark. Such eyes are defective in vision and the tattooing is simply to make the conspicuous white spot of such a color that it will not attract attention.

Blind eyes, due to injury or any other lesions which destroy the appearance and shape of the globe, may be covered with artificial eyes of glass so colored as to correspond with the normal eye on the other side. Anterior section may be required, if there is a prominence of the diseased eyeball due to anterior staphyloma. Mules's operation, in which a glass ball is inserted into the eviscerated sclera to give sufficient prominence to the globe, is a very satisfactory method of maintaining the prominence and the motions of the eyeball. The glass shell or eye placed in front of this has a much more normal appearance than when it is used after the globe of the eye has been entirely re-

FIG. 1.—New eye lid made with flap from forehead. Photograph taken three weeks after operation.

moved. A small eye due to atrophy may, if it is blind, be made to appear larger by wearing a strong convex lens in front of it. In front of the opposite eye a piece of plain glass may be inserted in the spectacle form.

In conditions of exophthalmos, and especially in that

form due to the disease called exophthalmic goiter, the disfiguring bulging of the eyes may be relieved by stitching the outer canthus of the eyelids so as to lessen the size of the palpebral fissure. This operation should not be done until the active symptoms of the disease have subsided. At that time, if the bulging of the eye persists, the removal of a little of the mucous membrane at the outer angle of the eyelids and insertion of a couple of stitches will so cover the eyeball as to make the bulging disappear.

There are many operations possible upon the eyelids which improve the appearance of the upper part of the face. The congenital condition called epicanthus, in which folds of skin extend over the inner angles of the eyelids, is improved by the removal of a vertical ellipse of skin at the root of the nose. Drooping of the eyelids, technically called ptosis, is remediable by removing a section of the skin of the upper lid or giving a new attachment to the elevator-muscle. Warts and other tarsal tumors are very disfiguring, but most of them are easily removed by simple operations.

Wounds of the eyelids should be made aseptic and sutured with care to prevent cicatricial distortion. One of the ugliest of the deformities of the eyelids is ever-

tax the ingenuity of the surgeon. Ankyloblepharon is another deformity difficult to deal with surgically. In it the two eyelids are united by cicatricial adhesion.

FIG. 3.—Ectropion of upper eyelid, due to cicatrization after avulsion of entire scalp. Operation consisted in using flaps from temporal region and side of nose. Incisions marked with ink. Head shows result of skin-grafting on ulcerated surface.

Various operations have been devised and are more or less successful.

FIG. 2.—New eyelid made with flap from forehead, taken at a later date than figure.

sion of the lid caused by cicatricial contraction following burns, lupus, or ulceration. Thoughtless surgeons sometimes cause this deformity by removing tumors of the face and placing their incisions so that cicatricial contraction drags the lower lid downwards or the upper lid upwards. This contingency should always be recollected in operations in the neighborhood of the eyelids. If the incisions cannot be placed in such a way as to make the drag of the cicatrix operate so as not to disturb the position of the eyelids, a plastic procedure to transfer the tension to another position should be adopted after the excision of the growth. Adhesion of the eyelids to the eyeball after burns of the conjunctiva are very difficult to repair with satisfaction. Many of them, however, may be relieved by plastic operations upon the conjunctiva or the transplantation of skin or mucous membrane. These conditions of symblepharon

FIG. 4.—Excision of epithelioma below the eye. Flap from temple used to prevent ectropion. Outline of flap marked with ink.

The plastic procedures required to make new eyelids, after their removal by sloughing or accident, or to fill

in a space left by the replacement of an eyelid which has been dragged outwards so as to cause ectropion, must be performed in accordance with the principles of plastic surgery already laid down. The various forms of skin-grafting will be of some value, but as a rule it is necessary to turn a flap of skin and subcutaneous tissue into the gap left by replacing the eyelid. The space left by the removal of this flap may then

FIG. 5.—Epithelioma near outer canthus removed, the space filled in with flap from temple, shavings of skin applied to surface left by transfer of the flap.

with advantage be covered with skin-grafts. It is usually better to thus utilize the skin-grafting process for covering the original seat of the flap than to depend on it for lessening the tendency to cicatricial contraction.

THE PSYCHOSES OF THE MENOPAUSE.

By JOHN B. CHAPIN, M.D.,
Pennsylvania Hospital for the Insane.

THE term "psychoses of the menopause" is understood to comprise the insanities that are caused, or occur, at the close of menstrual life in women. The term may be good enough, and a convenient one to use, if its meaning is intelligently accepted, and within proper limitations. It is not to be accepted and an error, to suppose that the insanities that appear at the menopause have special mental characteristics that are present only in women at this period of their lives, or that they differ from mental attacks at other periods of their lives, or in the opposite sex. To emphasize the psychoses of the menopause is an instance of an attempt to classify and describe insanities as distinct entities due to causes alone, and to open the door farther to an endless nomenclature and confusion as to the nature of insanity itself.

In both sexes, excepting the reproductive functions and organs essential to the continued existence of the race, there is an exact similarity in the brains and all other organs. Both sexes have the faculty of intelligence, sensory endowments, emotions, will-power, and memory. It is the change from the orderly and normal exercise of these faculties, which may arise from all of the experiences of life, that constitutes the condition commonly called insanity. Aside from some peculiarities that are characteristic and distinguish each sex, insanity in man is similar to insanity in woman, because it is the disorderly action of mental faculties that are common to both sexes. As the brain structure and cells, and the manifestations of various forms of insanity in each sex are similar, and when acted upon by like causes the results are the same, so we may reverse the reasoning and conclude that when insanity has appeared it has been induced by some lowered state of the general bodily health, the quantity and quality of the blood sent to the brain, and the degenerations proceeding from trophic changes, rather than by the absence or possession of any one of the organs of reproduction having only a sympathetic relation with the function of mentalization.

The menstrual life of women is commonly said to be about 34 years, beginning at 16 and ending near the age of 50. The function is a physiologic and not a pathologic condition, and it is just as normal a state of things that it should end as it is that it should begin.

This period of 34 years is the active portion of the life of woman. It begins and ends with two climacteric crises, between which she undergoes the sorrows of maternity, or experiences the worries—even at times her share of the struggles for existence—and the results of the "wear and tear" incident to living and advancing age, through all of which she may pass without damage to mind or body. Superadded, however, to the ills that come from various causes of an extraneous character, a certain proportion of both sexes have a neurotic heredity, or an inherited predisposition to mental disease, so that life begins on a lower plane, or on a descending plane. Every inheritance of the kind is a form of degeneration from a higher to a lower plane, lessening the powers of resistance against the tendencies to mental disease and unusual strains at every period of woman's life, and at the menopause. Clinical experience shows that the risk of insanity at the menopause, while it is believed to be largely exaggerated, is limited mainly to those who have a neurotic or mental heredity, and those who at the period of adolescence or during the menstrual life have had attacks of insanity. The transitions from the menstrual life which have been established perhaps for thirty years, to the new conditions of the menopause, are likely to be attended by changes in the body-weight, sympathetic disturbances, groundless perturbations, and even some psychic manifestations of an unusual character, but they need not alone or together arouse serious apprehensions. That the change in itself is a frequent cause of insanity does not appear from observation. Of the assigned causes of insanity in women in 8,320 admissions to hospitals for the insane, reported in 1899, 22 in 1,000, or 188, became insane at the menopause. These "causes" are to be accepted only with the qualification that they are called "assigned causes," and are often somewhat clouded by speculations of a personal character. Of the dread or risk of insanity at the approach of the menopause in a person ordinarily of sound health and

inheritance, it may be said they have no better foundation than a popular delusion based on borrowed fears.

If, on the other hand, to the neurotic or insane heredity and recurrent attacks of insanity during the menstrual life, from which perhaps complete recovery has not taken place, there be added a neurasthenic condition, sudden shock arising from domestic affliction or financial distress, causing insomnia, sorrow, and depression, then the menopause may become a contributory cause of insanity.

The psychoses of the menopause comprise hypochondria, simple melancholia, or prolonged mental depression without delusions, melancholia with depressing delusions, melancholia with agitation and motor excitement, or melancholia with stuporous conditions; acute delirium of grave import; or those alterations of character, developing gradually, attended by mental and moral degeneration, closely allied to those cases described as paranoia. There is a general agreement that melancholia is the most frequent form of mental disease at the menopause, and that acute mania does not occur as often. If the melancholia is prolonged for a year or more, and the patient becomes negligent of her habits, dirty, and destructive, incoherent in conversation, and has hallucinations, a further mental degeneration has taken place, and the prognosis is unfavorable. In other forms of melancholia the prognosis is favorable for recovery if the patient will take food, tonics, and in other ways cooperates with the physician. It is not the purpose to enter upon a clinical account of melancholia, or any form of insanity, occurring at the menopause, as they do not differ from the same affections in either sex, and at other periods of life in their course and ending.

During the past few years a number of women have been received in the Pennsylvania Hospital for the Insane who had been operated upon for the removal of the sexual organs, the majority of whom subsequently had melancholia with many of the usual symptoms attending the menopause, which had been anticipated by surgical interference, showing that whether the grand climacteric is brought on in the course of nature or by the methods of science, the mental results are quite similar when any have appeared.

It has been observed that many women who have been melancholy, or threatened with insanity at the menopause, have at the age of puberty also had serious neurotic or mental symptoms. This circumstance has been cited on which to predicate a probable recurrence at the menopause. The statistics of the Pennsylvania Hospital show that between the ages of 15 and 20, embracing the beginning of the menstrual life in women and the age of puberty in men, 284 men, and 276 women were admitted. Between the ages of 45 and 55, covering the usual period of the menopause, 975 men and 876 women were admitted into the same hospital. From these data it would appear, as far as they indicate anything, that at both of the periods named more men than women become insane. If the menopause alone was a serious and important factor in the production of insanity, it would so appear in the tables. I borrow further from a paper entitled, "An Analysis of 3,000 Cases of Melancholia" admitted into the Pennsylvania Hospital for the Insane, prepared by Dr. S. Weir Mitchell, which throws a side light on the subject we are now considering. Admitting that melancholia is the most frequent form of mental disease that occurs at the menopause, it would be a logical conclusion that a much larger proportion of cases of this form would

occur at this period. The exact percentage of cases between the ages of 45 and 50 was for men, 20 $\frac{1}{2}$; women, 21 $\frac{2}{5}$ —or practically there was no difference in the sexes.

It can therefore be stated that as a clinical conclusion that women who become insane at the menopause as a rule possess a neurotic and mental heredity; or have already suffered from recurrent insanities during the menstrual life; and are rendered unstable and peculiarly liable to a fresh attack at any crisis in their lives. The climacteric at the end of the menstrual life is approached by many with groundless apprehensions of some impending calamity; depression of the vital and physical powers at a time when there is a readjustment of activities, and the nervous forces take new directions to meet different conditions of life. In this sense it is a crisis and a cause of the psychoses of this period, just as depression of the vital forces, strains, worries and shocks produce insanity at other periods of life, and in both sexes.

The critical reader may correctly infer that while I have undertaken to present something about the psychoses of the menopause, and admit the term has some conveniences, I have further attempted to show that outside of the narrow limitations named there is no sufficient clinical experience to warrant the recognition of a distinct class of insanities as due to a normal ending of an animal function that is universal. If I am correct, then it is the province of our profession to remove the unfounded perturbations that worry and distress so many persons as they approach this period of their lives, and to hesitate about the performance of all those experimental operations that may precipitate it.

A CONTRIBUTION TO THE SIGNIFICANCE OF KOPLIK'S SPOTS IN THE DIAGNOSIS OF MEASLES.*

By JOSE L. HIRSH, A.B., M.D.,

of Baltimore, Md.

Associate Professor of Histology and Assistant to the Professor of Pediatrics, University of Maryland.

ALTHOUGH it has been more than three years since Koplik first called attention to the presence of a characteristic eruption on the buccal and labial mucous membrane in measles, the significance of his observations does not seem to have received the attention which its importance merits. A few scattered communications in this country and abroad have corroborated the findings of Koplik, but it is strange how slowly this diagnostic sign has made its way.

In December, 1896, Koplik's article on the "Diagnosis of the Invasion of Measles, from a Study of the Exanthem as it Appears on the Buccal Mucous Membrane," appeared in the *Archives of Pediatrics*.¹ He there described an eruption which appears on the mucous membrane, cheeks and lips during the invasion of measles from 24 hours to five days before a cutaneous outbreak. This eruption consists of small, irregular spots of a bright-red color; in the center of each red spot is the interesting sign, which is a minute, bluish-white speck. There may at first be only two, or three, or six such rose-red spots with the bluish-white speck in the center. The combination of a bluish-white speck with a rose-red background is absolutely pathognomonic of the invasion of measles. The spots are further characterized by

* Read before the Clinical Society of Maryland, February 2, 1900.

the fact that ordinary manipulation, such as brushing the finger over them, fails to remove them. When picked up with the forceps and examined microscopically they are found to consist of bacteria, chiefly diplococci, and epithelial scales. In diameter they vary from 0.2 to 1 mm. While at first few in number, they later may cover the whole inner surface of the cheeks and coalesce so that the whole buccal mucous membrane becomes of a uniform red color, studded with myriads of these bluish-white specks.

Koplik further pointed out that the eruption runs through a cycle. It appears 24 hours to 5 days before the eruption on the skin and when the skin exanthema appears and is at its height, the spots begin to fade and disappear. In order to see them they must be looked for by everting the mucous membrane of the cheek and lip, allowing strong daylight from a window to fall on them. I have never been able to see the spots by artificial light. When once seen the spots will be readily recognized, but to the uninstructed, various conditions may be confounded with them. It is to be remembered that the buccal eruption is alone significant and pathognomonic of beginning measles. The other eruptions on the hard and soft palate are of no moment as far as a positive diagnosis of beginning morbilli is concerned. In rubella and varicella an eruption is frequently found on the hard and soft palate and on the pharyngeal wall before it appears on the face; this eruption closely resembles the eruption found in the same locality in measles and differs markedly from the characteristic eruption found on the buccal mucous membrane in measles.

Food-remains in the mouth might be mistaken for the spots; of course, the former are not bluish-white, do not rest on a red background and may be readily brushed off.

Sprue is usually not limited to the mucous membrane of the cheeks, the tongue being also involved; the spots are whiter, more opaque and not surrounded by a red areola.

In herpetic stomatitis we have the appearance first of small yellowish-white (not bluish-white) isolated spots and subsequently the formation of superficial ulcers. That the normal "pearls" may be frequently mistaken for the measles-spots I have frequently seen illustrated in the dispensary by the students. Koplik² has called especial attention to this fact and observes that the "pearls" are minute yellowish-white specks shining through the normal epithelium which passes over them.

One of the earliest confirmations of Koplik's phenomenon appeared from the clinic of Prof. Heuber in Berlin; Slawyk,³ his assistant, reported a house epidemic of measles. In 32 cases the spots were observed 31 times; he observed them on the first and second days of the invasion, persisting for 2 or 3 days after the skin-exanthem appeared. Their absence in five cases of rubella and all other affections was marked.

A highly interesting communication by L. Knospel, from Ganghofer's clinic in Prague, appeared in the *Prager Medicinische Wochenschrift*.⁴ In 41 cases of measles the spots were constantly observed. In 17 of these cases the spots were observed before the skin-lesions; in 1 case five days before; in 6 cases four days; in 3 cases three days; in 3 cases two days; and in 4 cases one day. The remaining 24 cases were admitted with the cutaneous eruption, and all showed the presence of Koplik's spots. In 1 case he noted a

deposit of bluish-white spots on the gums. I have also observed this in one case (Case 8).

L. Havas⁵ has likewise reported 16 cases of measles in which Koplik's spots were found in the prodromal stage. In this country, besides the papers of Koplik, confirmatory evidence has been added by Sobel⁶ and Libman.⁷ Sobel reports 65 cases of morbilli in which the spots were constantly present, and in no other affection were they present. Libman reports 50 cases of beginning measles which showed the spots.

While the existence of Koplik's spots is of greatest importance for the diagnosis in the preeruptive stage of measles, their presence or absence may be a crucial test in the diagnosis of any morbilliform eruption. The absence of Koplik's spots in antitoxin rashes, German measles, erythema multiformi, urticarial eruptions, and macular syphilides, enabled Sobel to exclude the possibility of measles. One case of special interest was a young man in whom the eruption simulated in every way a macular syphilide; the presence of Koplik's spots, however, made the diagnosis of measles absolute.

In speaking of antitoxin rashes Berg⁸ says: "Although the chief manifestation of this complication consists in a more or less well-marked cutaneous eruption, this eruption has not, as is the case in acute infectious diseases, a constant and characteristic appearance. At one time it resembles scarlet fever, in another case urticaria, in one erythema, in another measles; and, strange to say, those cases in which the morbilliform eruption appears, occur generally from 9 to 14 days after the antitoxin injection, a period corresponding to the incubation of measles. In this connection La Petra⁹ reports a case of diphtheria in which six days after an injection a rash resembling measles appeared. The presence of Koplik's spots on the buccal mucous membrane enabled him to diagnose measles and to exclude an antitoxin rash. The further course of the case proved the diagnosis to be correct.

Measles may be complicated by almost any of the other infectious diseases—diphtheria, varicella, scarlet fever, typhoid fever, etc. The absence or presence of Koplik's spots is here highly significant.

My personal observation on this subject extends over a period of 2½ years. As chief of clinic in the children's department of the University of Maryland I have had the opportunity of examining the mouths of many hundred children. During this period I have seen at the dispensary and in private practice between 40 and 50 cases of measles; in every case in which the child was seen before the rash began to fade, the spots of Koplik were noted. I have found the spots most numerous on the buccal mucous membrane, sometimes limited to it, but not infrequently on both the buccal and labial mucous membrane, never elsewhere, with the one exception noted above in which similar spots were found on the lower gums. While many of the catarrhal conditions of children, such as tonsillitis, bronchitis, coryza, influenza, etc., simulate an invasion of measles, I have constantly noted the absence of the measles sign in these diseases. I have likewise failed to find them in scarlet fever, typhoid fever, varicella, or erysipelas. During this period no cases of rubella have come under my observation.

A recent house epidemic of measles in the Children's Ward, University Hospital, has enabled me to study a few cases in detail during the periods of incubation, invasion, and eruption. Of 10 children in the ward,

5 were attacked, all of whom showed the measles sign; of the 5 not so affected none showed any lesion of the mucous membrane. The histories of the cases in brief are as follows:

CASE 1.—Ernest P., aged 8 years, admitted December 26, 1899, and operated upon by Prof. Winslow for caries of the inferior maxillary. No history of a previous attack of measles. Temperature varied from January 1 to January 7, from 98.6 to 100°. On January 7, temperature 101° F., and on January 10, 102.2°. Between January 7 and 10, the patient complained of headache, coryza, and cough. On January 10, an eruption was noted about the face. I saw him for the first time on this date and on examination of the mouth observed numerous Koplik's spots on the buccal mucous membrane; no spots were observed elsewhere. The spots were present until January 12, when the cutaneous eruption about the face began to fade. The patient passed through a typical and uneventful course of morbilli.

Although this patient was isolated the day the eruption appeared, the other children in the ward had been sufficiently exposed to contract the disease. I was in consequence enabled to observe the other children during the period of incubation and invasion.

CASE 2.—Rebecca G., aged 3 years, admitted October 30, 1899, for contracture of knee and arm, following a severe burn. Previous history negative. On January 15, 1900, temperature rose to 102° F. Patient appeared dull; slight, cough; examination of mouth negative. On January 17, examination of mouth showed typical measles spots of Koplik on the buccal mucous membrane about the region of the second molar tooth. The cutaneous eruption appeared late the following day—about 30 hours after the buccal spots were first noted. The spots disappeared on January 20.

CASE 3.—Annie S., aged 9 years. Admitted December 29, 1899, for extensive burns of chest and arm. No history of previous attack of measles. Fluctuating temperature for some days prior to January 5, 1900, when examination showed a mild tonsillitis. Headache, coryza, and bronchitis were soon noted. The period of invasion was quite long. Examination of mouth continued negative until January 16, when the spots were noted on the buccal mucous membrane. The following morning the cutaneous outbreak appeared and remained evident for 4 days.

CASE 4.—Louis B., aged 3 years. Admitted December 11, 1899, for papilloma of the lip. Operated on by Prof. Winslow.

Child had never had measles. Temperature continued normal until January 15, 1900, when it rose to 100.6° F. Headache, coryza, conjunctivitis. Examination of mouth negative

until January 17, when spots were first noted on the buccal mucous membrane. The following day, a few spots were observed on the labial mucous membrane. The cutaneous eruption appeared on January 19, 48 hours after the spots were first noted. Spots remained evident until January 31.

CASE 5.—Irene D., aged 5 years. Admitted January 5, 1900. Cellulitis of forearm. Has been having elevation of temperature since date of admission, at times reaching 102°. January 17 she complained of photophobia and cough. Ex-

amination of mouth was negative until January 13, when a few Koplik spots were noted on posterior part of buccal mucous membrane; cutaneous outbreak appeared January 21, 72 hours later, and the buccal spots remained evident until January 23.

The two following cases are of interest from a negative point of view.

CASE 6.—Franklin L., aged 9 years, was admitted January 2, 1900, for incontinence of feces, with a history of an attack of rubella in early childhood. The temperature was normal until January 16, when it began to rise, until on January 19 it was 105.3°; pulse 140. Patient complains of headache and pain on swallowing. There is slight conjunctivitis and an annoying cough. Tonsils are enlarged and reddened. Physical examination of chest and abdomen negative. Repeated examinations of buccal and labial mucous membranes show no evidence of Koplik's spots. Diagnosis, la grippe. The further course of the disease substantiated the diagnosis.

CASE 7.—Frank M., aged 8 years. Admitted January 3, 1900, for contusion of buttocks. Had measles in earlier childhood. On January 16, slight elevation of temperature. Mouth negative. Complained of headache, nausea and vomiting. No pain referable to buttocks. On January 21 temperature 101.4. Koplik's spots absent. Blood showed a leukocytosis (11,000). Diagnosis, abscess of buttocks.

The remaining 3 children in the ward showed some elevation of temperature, but at no time exhibited any catarrhal symptoms and the buccal mucous membrane remained negative. In fact, in most all of the cases which I have cited, the child had been having an elevation of temperature due to the condition for which they respectively entered the hospital, thereby, to a certain extent, concealing the period of invasion of the attack of measles.

The diagnosis of morbilli in colored children is often very difficult, especially in dispensary practice, where an accurate history of the attack is difficult to obtain

from this class of cases. The characteristic rubecoliform eruption is seldom present, especially in full-blooded Africans. I have on several occasions been at a loss as to the differential diagnosis of urticaria, drug-eruption, syphilide, or measles. The following case in a colored boy is a typical example of this class of patients:

CASE 8.—George W., aged 19. Admitted to the male colored ward on November 9, 1899, for extensive gunshot wound of thigh and scrotum. No previous history could be obtained. He had been having a fluctuating temperature from date of admission. On January 19 he complained of headache; no cough or coryza. On January 24 an eruption appeared on the face and this soon extended over the rest of the body. I saw the patient for the first time on this day. The eruption was atypical; the boy was so black that the macular part of the eruption, so evident in white children, was entirely absent. The eruption could be felt better than seen. Examination of the mouth showed a few Koplik's spots on the buccal mucous membrane. The lower gums showed a deposit of bluish-white spots, a few of the spots coalescing into larger plaques. The boy had a typical attack of morbilli.

I am confident that had this case been seen when there was no epidemic of measles in his immediate vicinity (I should remark that some of the children went into this ward soon after getting out of bed) a diagnosis would have been in doubt, except for the presence of Koplik's spots.

Knospel has recently reported a case of measles in which the spots were observed in the second attack. That the spots are present in subsequent as well as initial attacks the following case, observed in private practice, will illustrate.

CASE 9—Marion E., aged 9 years, of wealthy and highly intelligent parents, so that I think I am justified in relying upon the statement of the mother that the child passed through a typical attack of measles 6 years ago. I saw this patient on the first day of the invasion of the present attack, as I was attending another member of the house for an attack of measles. The child has a slight cough, tonsillitis and coryza. The buccal and labial mucous membrane negative. The following day examination of the mouth showed a few spots on buccal mucous membrane. The diagnosis of the invasion of measles was then made and the child was put to bed with her affected sister. The cutaneous outbreak appeared 48 hours later. The child passed through a mild attack of rubecola.

The statement of Holt,¹⁰ and other eminent writers, that before the cutaneous rash a diagnosis of measles is impossible no longer holds good. By this new sign we are perfectly able to diagnosticate morbilli from one to five days before the cutaneous outbreak. The value of this buccal eruption, not only in the differentiation of measles from similar skin eruptions, but also in enabling us to isolate our cases much earlier than heretofore, a point of great importance in hospitals, orphan asylums and similar institutions, cannot be overestimated.

From a study of the above and many similar cases, I would present the following conclusions:

1. An eruption limited to the buccal and labial mucous membrane and characterized by the presence of an irregular red spot with a bluish-white center, is always present in beginning measles.

2. These spots are present from 12 hours to 5 days before the cutaneous outbreak.

3. The number of these spots bears no relation to the severity of the attack.

4. These spots will be found in no other condition of health or disease.

TWO CASES OF TRICHINOSIS WITH EOSINOPHILIA.¹

By WM. WATT KERR, M.D.,

of San Francisco, California.

Professor of Clinical Medicine, University of California.

In 1897, Dr. Thomas R. Brown, of Baltimore, called attention to the blood-changes occurring in persons affected by trichinosis. Since that time he has reported two other instances of the disease, and Professor William Osler has published a series of five cases, which includes the three described by Brown, all of which corroborated the original observations.

Dr. Brown noticed that in cases of acute trichinosis there is an extensive leukocytosis, with the eosinophiles in the blood absolutely and relatively increased in number. Associated with this was a decrease in the quantity of neutrophilic elements. An examination of muscular fibers showed not only the existence of myositis, but also the special prevalence of eosinophiles in the degenerated areas. The similar characters of the neutrophiles and eosinophiles, together with the inverse relationship in regard to numbers in these cases of trichinosis, suggested to Dr. Brown that the latter might arise from the former; and as both varieties of cells were particularly abundant in the infected areas, where also the ratio between them was much closer than in the general circulation, he concluded that, in all probability, the transition took place in the tissues. This opinion was still further strengthened by the discovery in the muscle of cells which appeared to be transitional forms, while they were absent from the general circulation.

Dr. Brown's theory is that the neutrophiles absorb toxins produced either by the trichina or as a result of its action upon the tissues, and that those toxins convert the neutrophiles into eosinophiles.

A few weeks ago Dr. W. T. Howard, Jr., of Cleveland, reported a case of trichinosis in which the leukocytosis was very slight, and in which there was not any excess of eosinophiles in the peripheral circulation. In this case a differential blood-count was not made, the cover-glass preparations were simply stained with the triacid stain and examined. However positive Dr. Howard may be of the value of such an examination, one cannot help regretting that all sources of possible error were not eliminated by a more thorough method. An autopsy was made twelve hours after death, and from examination of the blood in the tissues Dr. Howard reached the opinion that the eosinophiles were derived from the large mononuclear leukocytes and not from the neutrophiles. His line of argument is that in trichinized patients the large mononuclear cells are found to be increased in the general circulation, that in the

¹ Read before the Academy of Medicine.

affected areas these become plasma cells for which chemotactic substances, formed by the parasite or furnished by the degenerating muscle, have a strong attraction; and, finally, that these plasma cells are gradually transformed into eosinophiles. In the cellular reaction around the parasite varieties of cells were found which seemed to indicate this transition.

In view of these recent observations and the diversity of opinion the following cases will be of interest:

Charles Joy, aged 25 years, was admitted to hospital on November 6, 1899. For 12 days prior to this time he had been unable to work on account of severe pain and tenderness all over his body; every muscle in his body ached, it hurt him to straighten his limbs, and he felt as if his back were broken. He had suffered from vomiting for 2 days, the bowels were constipated, but his appetite was good. A herpetic eruption appeared on the left lower eyelid, the lower lip, and the lobe of the right ear.

Examination: The patient had an intelligent expression, his face was flushed, his pupils were large and reacted normally to light and accommodation. The eyelids were tremulous. The tongue was so painful as to be protruded with difficulty; it was thick, flabby, and dry, with red at the tip and edges, and white in the middle. The thorax was too tender to percuss; there was a slightly roughened inspiration over the upper portion of the right lung, and a few rales could be heard under the sternum. The sputum did not contain any tubercle bacilli or Charcot-Leyden crystals. A few rose-colored spots were seen on the abdomen; the liver and spleen were slightly enlarged, and there was tenderness on pressure over the liver, spleen and epigastrium. The patellar reflex was absent, the plantars were lively, but the toes did not move and there was no ankle clonus. The triceps reflex was well marked and there was fibrillary twitching of the pectoral muscles when they were percussed. Epigastric reflex was absent. Urine, specific gravity 1030, no albumin nor sugar; the diazo-reaction was obtained and indican was present in excess. The Widal test was made on four successive days, but no reaction obtained. The stools were examined at intervals, but no trichinae were ever discovered.

During the progress of the disease the patient suffered from attacks of nausea and severe gastralgia, drenching sweats, and the muscles continued to be very tender, although there never was any marked hardening. A piece of the triceps was removed on November 16, but no trichinae were detected until a second section was obtained upon December 8.

The first examination of the blood was made upon November 9; no plasmodia were found at any time. The accompanying table shows the results of the blood-counts made while the patient remained in hospital:

BLOOD-COUNT IN TRICHINOSIS.

CASE I.—JOY. November, 1899.

Date.	Red Cells.	Hemoglobin. Percent.	Leuko-cytes.	Polymorpho-nucleus. Percent.	Small Lymphocytes. Percent.	Large Lymphocytes. Percent.	Eosinophiles. Percent.
November 9	5,800,000		25,000	52.0	1.0	1.0	42.0
November 10	1,838,000	85	20,600	49.4	3.6	2.3	44.2
November 11				53.6	5.9	2.2	38.3
November 13				41.7	4.3	0.0	54.0
November 15				36.6	7.7	3.2	52.5
November 16				45.0	5.3	7.6	52.0
November 17			13,000	47.0	8.5	15.5	29.0
November 18				46.5	10.5	19.9	31.1
November 20				48.0	8.0	8.0	34.0
November 22				50.8	2.0	14.0	32.0
November 23				52.4	10.9	6.8	33.3
November 27			10,000	40.0	15.9	4.0	41.0
November 29	4,250,000			22.5	19.8	14.6	43.0
December 3				28.7	2.8	10.6	57.8
December 8				19.6	6.0	14.8	63.7
December 11				23.6	13.2	14.3	48.9
December 13				23.9	9.8	5.6	60.4

Y. Amanoma, a Japanese waiter, was admitted to hospital on the evening of November 17. He had muscular pains similar to the first patient, but there also was a hard elastic

feel to the muscles, especially towards their tendons. The face and body were edematous, and the pain was so great that the patient could not sleep. Diarrhea was persistently present, the diazo-reaction and excess of indican were again found in the urine; and in all respects this case resembled the former. He was recognized by the first patient as the waiter who had attended him in the restaurant where he had been in the habit of taking his meals. On November 22, a piece of muscle was taken from the gastrocnemius and in it trichinae were found in abundance. This patient had been suffering from gonorrhea for about one month before he was taken sick. The following is his blood-count:

BLOOD-COUNT IN TRICHINOSIS.

CASE II.—AMANOMA. November, 1899.

Date.	Red Cells.	Hemoglobin. Percent.	Leuko-cytes.	Polymorpho-nucleus. Percent.	Small Lymphocytes. Percent.	Large Lymphocytes. Percent.	Eosinophiles. Percent.
November 17				41.6	16.4	23.9	18.1
November 18			18,500	53.2	18.9	6.0	21.9
November 20			15,200	37.0	11.0	6.0	45.0
November 21				34.0	11.0	4.0	50.0
November 22				20.0	8.2	3.2	64.8
November 23			21,700	15.3	5.7	2.1	76.9
November 24				10.4	7.2	1.4	81.0
November 25			20,500	10.5	6.4	2.4	80.7
November 27	3,340,000	77		17.0	6.4	9.1	66.9
November 29			20,000	6.5	3.9	8.4	81.2
December 1				4.2	3.0	6.1	86.6
December 2				11.4	10.1	4.9	73.5
December 3			25,000	10.0	7.3	6.1	76.6
December 5				14.8	8.0	7.0	70.2
December 6				0.75	5.07	18.88	76.0
December 8				3.1	9.5	8.6	78.8
December 9				10.9	3.6	9.0	72.7
December 11				11.2	18.2	14.2	56.4
December 13				13.1	9.4	9.3	68.2
December 14	3,300,000		17,000				

The eosinophilia in this case may have been slightly influenced by the attack of gonorrhea.

Microscopic examination of muscle-tissue removed about 24 days after infection.

Muscle: Stains irregularly, particularly in areas about the trichinae. In these areas, where the staining is faint, the transverse striation lacks definition. In places there is a break in the continuity of the muscular bundles, with a curious curling of the ends of the fibrillae.

Sarcolemma: Apparently there is no thickening of the sarcolemma.

Muscle nuclei: These are greatly increased in number and are in all stages of degeneration and regeneration. Some appear as large faintly stained cells, having a small nucleolus concentrically or excentrically placed, and a greater or less degree of chromatin substance is present. Certain nuclei present 2 or 3 transverse constrictions. Large epithelioid cells with large nuclei were present among the muscle fibers and in the intermuscular spaces. Ziegler considers these to be transformed muscle nuclei.

Trichinae: These were found within the muscle tissue, either surrounded by the sarcolemma of a muscle fasciculus or in the supporting intermuscular connective tissue. The trichinae lay in coils surrounded by partially formed capsules, whose axes lay parallel with the long axis of the muscle fiber.

The capsule: A clearly defined structure lying between the muscular bundles, the poles of which consist of epithelioid cells embedded in a homogeneous matrix. Laterally there is a proliferation of muscular and connective tissue elements. At the poles, and infiltrating their entire neighborhood, were numerous small lymphocytes and a less number of eosinophiles.

Bloodvessels and blood: The capillaries were filled with red blood-cells, and an increased proportion of leukocytes (mononuclears and eosinophiles). The veins were greatly dilated with blood-elements clearly presenting the leukocytosis demonstrated by the blood count. The blood is found in the veins, capillaries and surrounding tissues; the leukocytes being the only extravasated cells. The blood in the infiltrated tissues is represented entirely by leukocytes (mononuclear and eosinophiles). The tissues so infiltrated

were the intermuscular connective tissue, the muscular tissue itself, and the capsule of the trichinae.

Leukocytes: The mononuclears, the eosinophiles a few polynuclears, a few large lymphocytes. The mononuclears were in greatest proportion about the capsular areas. The eosinophiles were most numerous in the rest of the tissue, *i. e.*, in the intermuscular connective tissues in the blood-vessels, and within the muscular bundles. The eosinophiles showed granulations wherever found, and all at the same stage of development. The polynuclears and large mononuclears were remarkable for their scarcity.

Summary: There were present those conditions described by T. R. Brown, the degeneration of muscle-fiber, the proliferation of the muscle nuclei, and the presence of eosinophiles in the connective tissues, and within the muscle bundles. No evidence of transition from polynuclears to eosinophiles was found. No plasma as such were found, but there was an abundance of regenerative muscle nuclei which are sometimes mistaken for them.

The blood-count in those cases showed the existence of a well-marked leukocytosis (25,000) in each. The percentage of neutrophils was persistently subnormal, and there was a strong tendency to an inverse ratio between them and the eosinophiles, although it was not by any means absolute. The eosinophilia in the peripheral circulation was well marked, the percentage in the case of the Japanese rising as high as 86.6.

The percentage of small lymphocytes was as persistently and extensively diminished as was that of the neutrophils, and showed almost as great a tendency to inverse ratio with the eosinophiles.

The percentage of large mononuclear lymphocytes varied exceedingly, sometimes being above normal, but more frequently within normal limits or subnormal; neither did these variations bear any relation to the number of eosinophiles. In the case of Joy eighteen counts showed it to be above normal (8%) seven times, below normal (4%) five times, within normal limits six times. In the case of Amanoma, in the counts made upon 19 days they were above normal six times, subnormal four times, and normal for the remainder. There was not any regularity in the rise and fall, and the absence of relationship between them and the changes in the eosinophiles is made very evident by the following comparisons:

Case of Joy.	Eosinophiles	%	Mononuclear	lymphocytes	%
"	43	"	"	"	14.6
"	41	"	"	"	2.8
"	48.9	"	"	"	14.3
"	52.5	"	"	"	3.2
"	68.7	"	"	"	14.8
Case of Amanoma.	Eosinophiles	%	Mononuclear	lymphocytes	%
"	21.9	"	"	"	6.0
"	45.0	"	"	"	6.0
"	86.6	"	"	"	6.1
"	76.6	"	"	"	6.0

So far as the blood-count is concerned the evidence in these two cases is opposed to the idea that the eosinophiles are derived from the large mononuclear leukocytes.

While the presence of what are believed to be transitional cells and an excess of eosinophiles in the areas of cellular reaction around the parasite warrant the hypothesis that in these cases the eosinophiles are developed in the affected tissues as a result of phagocytosis, it is possible, on the other hand, that the eosinophilia arises independently of this process, and that it is due to systemic poisoning from toxins secreted by the trichina; just as we find it in patients suffering from uric-acid diathesis where xanthin bases are formed in the intestine and absorbed into the system. With our imperfect knowledge of the origin and function of eosinophiles we are not forced to the conclusion that they are formed in the areas of local reaction simply because

they are more abundant at those points; they may be produced in the bone-marrow, as usual, and simply be attracted to these areas. In other words, they may not become eosinophiles as a result of phagocytosis, but eosinophiles may be the phagocytes that deal with this particular toxin. Neusser believes that gout, uremia, oxaluria, ankylostomiasis, injections of pilocarpin, or tuberculin, and many other known causes of eosinophilia produce xanthin bases which stimulate the sympathetic nervous system and hence the bone-marrow, so that eosinophiles result, and, it is possible, that trichinosis acts in a similar way. So far as I am aware no observations have been made on the blood of recent cases of trichinosis, but there can be little doubt that a powerful poison is produced, because, in many instances, severe symptoms of poisoning have appeared within a few hours after the infected meat has been eaten and before there has been time for tissue-invasion by the parasite. Probably in those instances, where immediate symptoms follow the ingestion of trichina, the disease has been in an active stage when the animal was killed, and consequently the flesh contains large quantities of free toxin; while in those where the symptoms are delayed the disease has passed into the quiescent stage and the parasites become encapsuled before the animal was killed, therefore it is necessary for the trichina to be set free, bring forth its young and enter into the stage of active existence before toxin is furnished in sufficient quantities to cause noticeable symptoms.

The variation in the degree of eosinophilia is explained by the fact that the female trichina continues to bring forth her progeny in successive crops during the 4 or 5 weeks of her reproductive activity.

The only point absolutely demonstrated by these cases is that in trichinosis we have a leukocytosis and eosinophilia which will aid in diagnosis even in doubtful instances; such as that of the patient Joy, where the blood-changes indicated the nature of the malady at a time when the symptoms were indefinite and examination of the muscle had failed to reveal the presence of the parasite.

In conclusion I would thank my clinical assistants, Dr. Ash, Dr. Wightman, Dr. Pope, and Dr. Ebricht, to whose faithful work in our clinical laboratory the important features of this communication are due.

Since this paper was written the report by Blumer and Neuman of 9 cases of trichinosis has appeared in the *American Journal of the Medical Sciences*. Their results in regard to the various leukocytes found in the peripheral circulation correspond with those we have just mentioned.

PHYSICAL DIAGNOSIS IN ITS RELATION TO THE STOMACH AND ASSOCIATED ORGANS.¹

By B. C. LOVELAND, M.D.,

of Syracuse, N. Y.

I WILL endeavor to point out briefly what may be learned regarding the stomach, liver, pancreas, spleen, and kidneys by the physical means at our command, *viz.*, inspection, palpation, percussion, auscultation, and the joint use of the last two means, which is called auscultatory percussion.

Inspection will be considered under two heads, general and local. The general appearance of the patient

¹ Read before the Syracuse Academy of Medicine, January 23, 1900.

always should be considered, no matter how trivial or how serious his complaint may be in his own estimation. He may say that he has enjoyed perfect health till within three months, and is only a little run down, yet he may, as I have observed more than once, show a profound prostration of his nutritive system with the marked cachexia of advanced malignant disease, a condition that may show little or no positive signs by the other means at our disposal. He will grow rapidly worse and die, while another complaining of much more in the way of subjective symptoms, with a worse history perhaps, may present a very healthy appearance, and have no serious disease. Hence, even when we suspect only stomach-trouble, we should note carefully the general appearance of the patient as regards age, quantity and quality of flesh, color and condition of the skin, not being satisfied if the patient is free from jaundice. Note the color, dryness or moisture, and integrity of the mucous membrane of the lips, and take the same care in noticing the condition of the gums, throat, and teeth. The tongue should be examined with regard to its firmness, color, and coating, and both the distribution and character of the coating should receive attention.

The careful observation of these outposts on the way to the stomach will give some idea not only as to the patient's general state of nutrition, but may point quite sharply to something for study when the local examination is taken up.

The *temperature* also should demand attention, as in acute gastritis it may be considerably elevated, and often in the later stages of cancer it will be found to be constantly a little above normal. An illustration or two will serve to emphasize the importance of a careful inspection. The mapped tongue, bright red oval spots occurring usually on the anterior half of the tongue, while the rest of the organ is thickly covered with a white fur, the red enlarged papillae near the tip, and the tremulous condition when protruded are well known indicators of functional nervous disease. The pale, thick, flaccid tongue, when the general appearance is a sort of leathery pale color, would suggest strongly cancer. Yet it is possible for cancer to go on to a fatal termination without this characteristic color. The aphthous patches, and fissures in the mouth and lips of the patient suffering from chronic wasting disease, show increasing seriousness of the situation. The thick, brownish or yellowish coating on the back of the tongue, often piling up thickly around the circumvallate papillae, so commonly called the bilious tongue, hardly needs mentioning.

Local Inspection.—All clothing should be removed from the trunk between the arms and hips to secure an unobstructed view of the portion of the body to be examined. Note now the color and condition of the skin, as it may give a different impression than that gained by observing the hands and face. The surface bloodvessels should not be overlooked, as in obstructive internal disease the surface veins will often present a varicose condition. A condition of varicose venules or capillaries in the skin over the sixth to ninth ribs on each side is often associated with sedentary habits, and the so-called bilious or lithemic habit, and frequently points to a congestion of the underlying organs. Observe the shape or form of the chest and abdomen while the patient is standing, then observe again while the patient is on his back with the knees drawn up. A bulging of the lower ribs and upper part of the abdo-

men may sometimes be seen in cancer of the liver and in hypertrophic sclerosis before ascites has appeared to such an extent as to make the whole abdominal wall protrude. Another feature often associated with malignant disease of the stomach or pancreas is a sharp dip in the abdominal line at about the ends of the tenth rib, the abdomen again showing more fulness or rotundity from the umbilicus down to the pubis. This is best noted from a side view while patient is on his back with his knees drawn up, and sometimes there is also a line like that where the wrists are habitually bent. This line may occur also in chronic dyspeptics who are accustomed to sit in a stooped position.

Palpation.—This method of examination should be employed in all cases of suspected trouble in the region of the stomach; is best practised while patient lies on his back with the legs flexed; but if gallstones or prolapsed kidney are among the possibilities, much is to be gained by turning the patient on the side, or possibly employing the sitting posture.

By palpation may be outlined points of tenderness, gastric ulcer being a marked example; unusual heat as in localized inflammation; tumors or indurations of the pylorus or greater curvature of the stomach; marked increase in the size of or nodules on the surface of the liver; enlarged or distended gallbladder; prolapsed or enlarged kidneys. Very little if anything can be learned about the pancreas unless it happens to be the seat of cystic or cancerous disease, which has gone so far as to make a considerable tumor, and even then it is hardly possible by physical methods alone to ascertain positively its condition, on account of the depth of overlying structures. It may be said that a distinct tumor located in the walls of the stomach is very suggestive of cancer, though a few cancers in that region are not marked by tumor, and occasionally marked tumefaction occurs in connection with gastric ulcer and chronic catarrhal gastritis. I am aware that my statement in regard to the last-named disease does not conform to the table of differential diagnosis by Welch, quoted in the last edition of Pepper's Practice, in which he says that chronic catarrhal gastritis has no tumor.

Among the obstacles to successful palpation are rigidity of the abdominal walls, fecal accumulations, and great distention with gas or fluid. It may be necessary to etherize in order to reduce the rigidity, or to practise palpation while the patient is in a warm bath, as recently suggested by Dr. Hemmeter. If in the stomach, distention with gas may be relieved by the tube or by flushing the colon if that is the seat of the troublesome distention. The tube also would clear the way for diagnosis by palpation in such a case as I once saw in which the stomach was dilated with fluid contents to such an extent that gentle pressure with the hand just above the pubic arch ejected fluid from the mouth. The stomach in this patient contained more than a gallon, as evacuation showed. (Fig. 1.) Its greater curve passed from the border of the ribs at the extreme left of the abdomen down to the iliac fossa, thence across close to the pubic arch to the right iliac fossa, thence upward about to a point midway between the crest of the ilium and the umbilicus, where was located the displaced pylorus. The lesser curve passed from the ensiform cartilage downward and to the right, where it met the greater curve. When this stomach was filled the outline described was distinctly visible on inspection; when empty a tumor was easily felt at

the pylorus. The patient was much emaciated, but free from the usual pallor and cachectic appearance, but died of cancer as the autopsy verified. Another rare case in which inspection and palpation gave the

FIG. 1.—Mrs. M, 47 years. Cancer of pylorus, extreme limit of dilation; great emaciation, but no cachexia nor marked anemia. Death from inanition. Autopsy.

clues from which to form a diagnosis resulted fatally; the only diagnosis that was made was a tumor in the pelvis. (Fig. 2.) The autopsy revealed the tumor to

FIG. 2.—Mr. S. Cancer involving pyloric half of stomach with closure of pylorus and great displacement but no dilation. I was asked to conduct the autopsy, but did not see the patient.

be a cancerous stomach, the walls of which were thickened and contracted till it formed a tumor about 2 or 2½ inches in thickness, involving the pylorus and extending two-thirds of the way to the cardiac portion. There was great displacement but no dilation. When there is thickening from any cause, and sometimes when there is no thickening, abdominal pulsation may frequently be felt, not a serious sign, yet often giving the

patient much anxiety, and once, at least, I have known this to be mistaken for abdominal aneurysm.

Filling the lungs with air makes the liver drop further below the ribs, and may be of service in feeling for nodules on its surface. It is often difficult to differentiate a tenderness of the gallbladder incident to cholecystitis or small gallstones from pyloric tenderness caused by catarrh in that region. Help in clearing up the matter can be obtained by placing the patient on the left side with knees drawn up, thereby giving nearer access to the gallbladder, sometimes enabling us to feel calculi not palpable in the dorsal position. The spleen in health is not palpable.

The kidneys may be easily palpated with sufficient thoroughness to ascertain any enlargement or unusual position. The patient should be placed on his back with the knees flexed and abdomen relaxed, and palpation should be practised with one hand placed under the back just below the ribs, the other compressing the abdominal wall so as to bring the kidney between the two hands, if it is enlarged or displaced.

Percussion is a method of eliciting sound by stroking over the surface of the body, which sound, varying in pitch with the density of the subjacent organs, enables us more or less accurately to outline their dimensions. Historically we are acquainted with a direct method, dating back to Hippocrates, known as immediate percussion, but practically we only use the method known as *mediate*, which is practised by the interposition of a substance between the body and the stroking instrument. Numerous devices have been made both for making and receiving the stroke, but nothing has ever been invented that has any material advantage over those instruments which Nature gave us, the human fingers. The main drawback to the finger as a pleximeter is that it may become tender or even sore if it is used constantly for that purpose.

By percussion we may outline on the surface of the body, with a fair degree of precision, the position and size of the stomach, liver, and spleen, and also the colon. The normal position and size of the stomach would be about from the lower border of the fifth rib about 2 inches to the left from its sternal end, to the left and downward to the point of union of the bony and cartilaginous portions of the ninth rib, thence following the curve still downward and to the right, to a point 2 or 3 inches above the umbilicus, thence upward and toward the right to a point just under the cartilaginous portion of the eighth rib, and about 3 inches to the right of the median line, which is the location of the pylorus. The lesser curve can be much less accurately traced on the surface, due to the fact that it is covered by the left lobe of the liver, which interferes with the percussion-sound, but it passes from the point mentioned as the termination of the greater curve slightly downward and to the left, then almost perpendicularly upward to a point on the lower border of the fifth rib about an inch to the left of the sternum. The tympanitic sound of the stomach may be differentiated from that of the colon by changing the amount of gas in one or the other, either by evacuating it by a tube or by forcing air into the rectum by a bulb-syringe. When it is desirable to fill the stomach with gas to better define its outline, it may be done by the use of an atomizer bulb attached to an ordinary stomach-tube, or by drinking first one and then the other parts of an effervescent powder, allowing it to throw off its gas in the stomach. When the last expedient is

resorted to, however, it is well to have a tube conveniently near to relieve overdistention in case the patient becomes distressed by it. In disease of the stomach, notably in cancer, both dilation and displacement are apt to occur, and sometimes one or both occur to a remarkable degree, as noted earlier in this paper. But we may find dilation and displacement to a considerable degree without malignant disease, simply from an atonic condition of the muscular structure. Another occasional cause of dilation of even an extreme degree is cicatricial contraction after ulceration, and such contraction may produce very odd shapes in the stomach by reason of the location of the cicatricial tissue, the dilation occurring above or toward the cardiac end. One of these forms, at once contracted and dilated, is called the hourglass-stomach.

The dilation affects mainly the greater curve, and when the obstruction is at the pylorus, or when the cause is atony of the muscular coats, the greater curve is increased symmetrically throughout its entire extent. If, in extreme or even considerable dilation, evacuating the stomach reveals long-retained and undigested food, even if there is none of the "coffee-ground" material, it is very strongly suggestive of cancer. Once a patient, quite well nourished, came to me complaining of chronic acidity of the stomach of years' standing. She was not cachectic, and had suffered only a moderate loss of flesh. Twenty-four hours after the first consultation she spontaneously evacuated her stomach, and in its contents were found fiber of watermelon which she had eaten five days before, and prune skin which, according to the best information that could be obtained, had remained in her stomach 11 days. No tumefaction could be felt, partly because she was quite fat, but a diagnosis of cancer was tentatively made, and within a week was confirmed by the characteristic vomit. Very considerable dilation existed. The patient went to her home, passing from immediate observation as soon as the diagnosis had been fully made, and died within two months. However, contrary to this case, instances can be given where considerable digestive power was retained for a long time after cancer of the pylorus had so far advanced as to make the diagnosis clear. Dilated and prolapsed stomachs are much more common in women than in men, are often associated with general weakness of abdominal and pelvic muscles, and prolapse of the kidney or other portions of the pelvic contents.

Percussion is usually practised while the patient lies on his back, but when, as in the case with the stomach, the organ undergoing investigation may be filled in part with fluid and in part with gas, changing the position to the side or even to the erect posture may help in marking out a more definite outline.

There is frequently confusion of diagnosis between gallstones or hepatic colic, and neuralgia of the stomach, and not infrequently cancer of the pylorus is associated with cancer of the bile-ducts or under surface of the liver, but percussion alone does not give much aid in clearing up the matter unless in such an enlargement of the liver as suggests cancer, and that would not be an early sign. What may be learned about the liver by percussion may be briefly summed up as follows: A dulness on percussion marks its width from above downward, in health about a handbreadth, which will be from the fifth rib to the free margin of the costal cartilages, measured on the line of the nipple. This is the point of greatest width. The area of dulness gradu-

ally diminishes toward the left with percussion over the left lobe, but the dulness may be elicited over nearly the same width on the right side quite around on the back. Any variation in size may be noted, smaller even to two or three fingers' width, in atrophy or sclerosis; larger, even reaching to the iliac crest or the brim of the pelvis in some cases of cancer or hypertrophic sclerosis.

The spleen may be located by percussion quite well around to the left side, and extending from the ninth to eleventh ribs. It, like the liver, is subject to great enlargement in malarial and some other conditions, in which it may be outlined by percussion.

Auscultation.—This method of investigation, except as combined in the method called *auscultatory percussion*, is of little use in studying the stomach and neighboring organs. It may be useful, however, in determining the extent to which a tumor compresses the aorta, as one case seen some years ago in which an enlargement of the liver had progressed to such a degree that it compressed the aorta, producing a distinct bruit. (See

Fig. 3.—Mr. H. C., 50 years. Extreme enlargement of the liver from hypertrophic sclerosis of the liver; compression of vena cava gave distinct bruit; a thrill could be felt below the point of pressure; anasarca and ascites existed; death resulted.

Fig. 3.) It will be noticed also that the more dense the tissue the further the heart-sound will be heard. Succussion-sounds may be induced when there is dilation of the stomach which will aid us in determining the power of the stomach to empty itself. Another condition in which the ear will give us a clue of some significance is that occasionally found in women who complain that each time they take a full breath it produces a gurgling sound. Such a condition is of course distressing, and is caused by a dilated stomach filled in part by fluid and in part by gas, and the constriction at the waist-line is sufficient to make the diaphragm force some of the fluid from below the constriction at each contraction, the fluid gurgling back during relaxation. (See Fig 4.)

Auscultatory Percussion.—This method does not figure strongly in the textbooks, but I think when properly used it is as much more reliable in its results than ordinary percussion, as auscultation aided by a good

stethoscope, or phonendoscope, is more accurate than using the ear unaided. I am sure that all that would be necessary to convince one of the advantage of this method would be to let him try to outline the liver or stomach of any ordinary patient by percussion, marking his results on the skin, then repeat the performance with the phonendoscope, using the small foot-piece, and tapping gently with the index-finger, marking the skin also and compare results. A much more complete outline would result from the latter procedure. Auscultatory percussion may be practised with the ordinary stethoscope, but from experience I have come to like the phonendoscope better. It is almost or quite impossible to outline the left lobe of the liver, or that portion of the stomach which is covered by the liver by ordinary percussion, while either can be easily and fairly accurately done by the auscultatory method. The latter method has considerable advantage also when the abdominal wall is thickened by the accumulation of fat. Of course either method of percussion to be suc-

FIG. 4.—Mrs. M., 41 years. Nervous dyspeptic; atonic dilation, somewhat excessive; pylorus normal in position. When she was dressed a gurgling sound was produced at each breath. Splashing sounds also existed. Recovery.

cessful requires some training of the ear to detect slight differences of sound.

In closing it may be well, after taking up the methods of physical investigation separately, to recapitulate a few of the more important points to be gained by such an investigation. We may determine the location, size, shape, presence or absence of induration or tumefaction, in the internal organs, and in many cases the character of tumefaction if such exists, and also the sensitiveness on pressure. This information may be secured in relation to stomach, liver, spleen, or kidneys by purely physical methods, and when we have the opportunity to add to this the history and symptoms, and in selected cases the chemical analysis of the contents of the stomach, and urine, and an examination of the blood, in addition to the clinical appearance, there will be very few cases in which any serious doubt as to the exact diagnosis will remain long in our minds. And yet in the face of some very perplexing problem in diagnosis we may console ourselves with the fact that on rare occasions cases occur so negative in all the signs, both

physical and clinical, that they will defy the diagnostic ability of the most experienced. Such consolation, however, should not be ours until we have gone so thoroughly into the case as to leave nothing undone which might add to our knowledge of that particular condition.

Tuberculin as a Diagnostic Agent.—Veranus A. Moore (*Albany Medical Annals*, June, 1900) says that tuberculin in the dose necessary to bring out its diagnostic effect is absolutely harmless to a healthy animal. Cases of septic infection following its use must be attributed to other causes. In tuberculous animals it produces a rise in temperature which, within certain limits, follows a definite course, usually terminating in from 18 to 24 hours after the injection. The temperature usually begins to rise in about 8 hours, giving a steady but quite rapid elevation for from 1 to 3 hours, a continuous high elevation of from 4 to 12 hours, and a gradual decline. This is practically constant, be the rise moderate or extreme. In addition to the elevation of the temperature there is sometimes a marked nervous chill. Since the reaction is apparently the result of the affinity between tuberculin and living tuberculous tissue, when the two are brought together in the same animal this reaction almost invariably takes place; exceptions being when there is no reaction and no disease found (a beginning lesion not larger than a pea may cause pronounced reaction and yet be difficult to find, especially if located in the marrow of a bone), and when there is no reaction and the disease exists (advanced cases often fail to react, but the disease can then be detected by ordinary clinical methods). Not over 5% of errors exists in interpreting its effects when applied by the ordinary practitioner and even those unskilled in its use. [M.B.T.]

A Brain Tumor: Operation and Recovery.—Mills (*Journal of Mental and Nervous Disease*, May, 1900) reports the history of an exceedingly interesting case of brain-tumor in which the diagnosis was beset with numerous difficulties. The patient, a man of 57, at the age of 42 became nervous, emotional and despondent and suffered from headaches. He spent about two years in Europe and recovered almost entirely, with the exception of an occasional headache. Ten years later he suddenly noticed an unpleasant sensation in the right arm, apparently some form of formication. These attacks recurred at intervals of days, weeks, or months, lasting only a few moments, but followed by a sensation of heaviness. He became neurasthenic and despondent, and suffered with a feeling of distress in the head. For 5 years he was able to attend to his business, but then began to notice awkwardness of the right upper extremity, followed by awkwardness of the right leg, and was frequently hysterical. There was distinct ataxia in both right extremities and impairment of sensation to pain, touch, and temperature over the right half of the body. There was slight diminution of hearing, smell, and taste on the right side, although this was variable. There was slight exaggeration of the tendon reflexes. At first Babinski's reflex was absent, but subsequently it appeared. About 5 years later he began to suffer from amnesia, had difficulty in writing, and was rapidly fatigued by any intellectual work. Optic neuritis was never present. Shortly after this there was some inequality in the pupils and slight ataxia of the left arm. The amnesia increased, and there was some pain in the top of the head. In view of these symptoms tumor was diagnosed and located in the left superior parietal lobule. An operation was performed by Dr. Keen, and a tumor weighing 11 grams was removed, together with a cyst about 10 cm. in depth. After a period during which the amnesia was more extreme and there was complete paralysis of the right side, improvement commenced and progressed slowly but steadily until the patient was able to walk and to use his right arm with considerable freedom. Sensation was completely restored, the amnesia disappeared, and the intelligence was normal. The chief difficulty in the diagnosis was in the exclusion of hysteria, for throughout the whole course of the case, contraction of the form fields and the reversal of the color fields were present. The tumor was examined by Dr. Spiller, who considered it to be a perithelioma or endothelioma. In its neighborhood he found marked alterations in the cells of the cortex. [J.S.]

Public Baths and Communicable Diseases—The most careful observation of sanitary requirements must be observed in the management of public baths in order that they may be of sanitary value. The public bath-house may be made a medium of filth and disease rather than an aid to health and cleanliness. Those who are most benefited by public baths are usually most careless of their persons and are most likely to be afflicted with communicable diseases. The attention of the health-authorities of New York has recently been drawn to an epidemic of ophthalmia said to be due to bathing in contaminated water. Some of the earlier attempts to maintain public baths in Philadelphia were abandoned because of the danger of infection, and while those now in operation are managed with care this danger must not be overlooked. Plenty of water is one great essential. The water in the pool should be in constant motion and constantly renewed. On purely hygienic principles—the purpose being cleanliness and coolness—the best thing would be a series of shower-baths. From these all the good results of the pool could be obtained without the danger of personal contamination.

Idolatry in Code-worship is a tendency that seems more and more prevalent. One of the most honored and honorable of American physicians recently protested that consultation with sectarians and stealing patients was more prevalent with some code-worshippers (citing the cases of some principal officers of great medical organizations) than with practitioners excluded from the ranks of the faithful. There is, of course, a usefulness in the antiquated code, but we should not forget that zealots are prone to worship the idol rather than the spirit it represents. Idolatry may be as bad as or worse than atheism. Certainly there is no reason for pride on the part of the idolaters, who disobey the spirit of ethics in their practice, and who excuse the most outrageous professional scoundrelism if it happens to be exhibited by the code-worshippers. One should set his own household right before lecturing his neighbors. It is a standing disgrace that all reputable regular physicians cannot join our national medical organization because of a silly war of words. All who love our profession more than their "logic," cliquism, or vanity, will surely try to find a common meeting-ground and a method of uniting upon essentials.

"Ex Occidente Lux."—In a recent lecture in London, Dr. Osler is reported to have said that before many years the European medical student would be found spending his year or two of postgraduate study in the United States. If men governed their actions by the logic of facts we could not doubt the fulfilment of the prophecy. We certainly believe that, except for other purposes than practical medical scientific work, the American student can do better now than to go abroad. Few realize what tremendous progress has recently been made in our home-clinics, and in many respects how far superior they are to the foreign ones. In one department of medicine—dentistry—American superiority is universally admitted. At the present rate of advance, it will become true of other specialties. In ophthalmology it is positively ridiculous to think of an American oculist learning anything of value elsewhere than at home, and we wish the European masters would come to our own ophthalmic kindergartens. *Ex Oriente Lux* has been the law of science up to the present time, but the extreme West having been reached by the light of civilization, there is nothing left but a reflex or a reversal of the law, and in many things besides medicine the illustrations are multiplying fast. Principles and theories are valueless except for realization and translation into facts. We may have been taught, we may still be taught, the theoretic principles of our art, but in their practical application we are the better teachers. It is in no spirit of boastfulness that we speak, but to encourage our profession to perfect the science, and especially the art, the practice, or the mechanics of medicine—a work in which we are exceptionally fitted to excel. Here is a most legitimate field for patriotism.

Secondary Education and Medical Education.—At first thought there seems to be a very great gap between the education of the common, grammar, and high schools and that of the medical schools, yet this very early training of the boy has the greatest possible influence on his future when he enters his medical studies and practice years later.

Those interested in secondary education were no doubt reminded by the notices of the recent death of that pioneer in education, Henry Barnard, at the ripe age of ninety years, of the condition of general education in 1840, when Barnard and Horace Mann were

beginning those reforms in the common schools of Massachusetts and Connecticut which have revolutionized the educational system of the whole country. Since those days great progress has been made, but there is still room for much improvement. One greatly needed change is that our students shall graduate from medical schools younger. This cannot come by shortening the medical course; it should not come from the omission of a general college and scientific training. The only alternative is that the secondary schools fit their men for college two years or so younger than at present. This is by no means impossible; those acquainted with the educational systems of Germany and France know that their students enter their professional training about two years younger than is customary with us and yet their general education is better if anything than that of the American student. In an essay entitled "Can school programs be shortened and enriched?" President Eliot of Harvard (*Educational Reform*, Century Co., New York, 1898) compares the programs of French and American public schools in tabular form, much to the disadvantage of the latter. Physicians should be public-spirited men and should lend their intelligence and influence to aid in bringing about these reforms in shortening and enriching public school programs which are so important for the general good as well as for the advancement of the profession.

The problem of hospital organization has occupied the attention of some of the ablest executives both of this continent and in Europe. That the hemispheres have arrived at very opposite solutions is an indication that one or the other or both are wrong. Hillis (*Medical News*, July 7, 1900) has recently contributed a long article upon this subject in which he takes occasion to attack, by means of imaginary hospital episodes, the method particularly practised in this country, that is—of having interns of fixed and progressive term of service, while the responsible work of the hospital is assigned to a visiting staff composed of distinguished practising physicians. While some of the pictures given by Hillis appear to be overdrawn, there can be no question that in the main they represent conditions that not infrequently occur. Very naturally, the unsalaried visiting physician, who in some cases looks upon his connection with the hospital more as an honor and possibly as an advertisement than as an opportunity to do serious scientific and clinical work, neglects his duties whenever his paid outside practice demands his attention. This necessarily throws the responsibility of the care of the patients upon the interns, and although one can say that, in general, they do their work wonderfully well, considering the brief training they have had and the limited opportunity for practical work offered by nearly all our medical schools; nevertheless, they do not do the work as well as the interested

patient has a right to demand that it should be done. Hillis suggests a remedy for this condition which is we think not altogether adequate. He would have permanent residents in the hospital, that is, he would have retained in the service of the hospital for an indefinite period of time, residents who have demonstrated their ability, and would give these residents, under the visiting chiefs, the charge of the services. It is inconceivable that, with human nature constituted as it is at present, there would not speedily be a serious conflict between the visiting chiefs, who take after all a more or less desultory interest in the wards, and the permanent residents, who by their constant attendance would soon acquire the feeling of being the most important element in the whole hospital organization. It seems to us that our European friends have done well in this matter. The position of visiting surgeon, or physician, as the case may be, is one not only of honor but of profit, for a salary is attached to it; the hospital, therefore, acquires a right to the services of these men, and can compel them to make thorough rounds and to spend at least several hours every day in the hospital attending to the needs of the patients. As a result of this, the diagnosis, the treatment, the operations are entirely in their hands and under their direction, and although the interns occupy a decidedly subordinate position, their opportunities for acquiring accurate knowledge and skill in their profession are vastly greater than the corresponding opportunities in America, and therefore leave the hospital better men and more able to fill important positions. There is another very desirable result of this system—it gets rid of all the superannuated attending physicians and surgeons. Hillis thinks that the old surgeon who still hangs on to his hospital appointment and attempts to operate now and again is worse than an active bullet "plowing," as he expresses it, "through the solar plexus of a patriot." Far be it from us to endorse this startling simile. Affairs are not perhaps so calamitous as he depicts them, but the time when hospital positions will mean pay to and require work from the visiting staff seems sadly distant in this as yet imperfectly (medically) civilized land.

A Collegiate Course as a Preparation for Medical Study.—The action of some of our leading medical schools in requiring an academic degree for entrance to their courses has been severely criticised by some. It has been maintained that if three or four years be devoted to a more liberal education the graduate in medicine enters upon his professional career too late in life; that the studies of most colleges are not such as best fit a man for medical work, and the student's time is wasted; that college men are apt to become dissipated and waste time; that the higher requirement shuts poor but deserving men out of the profession because of added expense, etc. There is a certain amount of

justice in these criticisms; the majority of men do enter the profession later than is desirable, some colleges do still allow too little liberty to their students in elective studies, some students waste their time; but is this the rule? are these disadvantages unavoidable? We think not. We know a goodly number of young men of average ability, who, through proper training, were able to enter the classes of some of our leading colleges and universities as young as sixteen or seventeen. This is not above the average of the French or German student, and by proper planning and with efficient teachers it is possible for almost any boy. There is considerable difference of opinion as to the course of study most desirable as a preparation, but with the various curriculums of our leading institutions it would not seem difficult to find one suited to the needs and tastes in almost any case. The tendency with leading educators at present seems to be to advise a course which includes little of the old-fashioned classical and mathematical training and much of science, English, and modern languages. With the liberal elective systems of nearly all our colleges, it is possible to arrange a very satisfactory course of this kind, and in many institutions a special course preparatory to medicine is given. Entering upon such a course at the age of sixteen the student can obtain both the collegiate and medical degree by the age of twenty-four, which is certainly as young as most men are fitted to take up the responsibilities of medical practice.

Few will deny the value of a good collegiate course. Every professional man should have sufficient command of his native tongue to be able to express his thoughts fully, clearly, forcefully, and correctly; and it is highly desirable that he should know something of its splendid literature. The physician should be able to command the attention and respect of the members of his own profession and of the public, when he feels called upon to present his views before them; he should be able to take part in the proceedings of societies and other professional meetings, and to put his thoughts in suitable form for publication in the journals of his profession. To acquire such power of correct use of English necessitates thorough, early training and practice under the guidance of competent teachers. The student who enters the study of medicine after a thorough course of study, including efficient laboratory work in chemistry, physics, botany, zoology, and comparative anatomy, already has an ability to observe accurately and to draw conclusions from his observations that is certain to give him a great advantage over his fellow student who has not had such training. Moreover, the great amount of highly important scientific work which is constantly being done by French and German investigators and clinicians is so great that no one can claim to keep abreast of the times who is unable to read in the original scientific articles written in these two languages.

While some men may be found in every college who

are dissipated, and more who dawdle away their time, this is not general. On the contrary, the atmosphere of college life is invariably stimulating and elevating as is evidenced by the large number of the leaders in the intellectual and moral progress of the times who acknowledge their indebtedness to their early college training. With the large number of free scholarships and opportunities for earning money during student life scores of men have found it possible to make their own way through college, and it cannot fairly be claimed that any intelligent and deserving man need be debarred from a liberal education because of poverty.

We would not advocate that every student should follow an absolutely fixed course of study, but that he should take *some* thorough course of preparatory study and that the general trend of such studies should be along those lines which will help him in his future career. The importance of this can be hardly overestimated. The lack of adequate preliminary training is the greatest weakness in the present system of American medical education. According to the Bulletin of the University of the State of New York on professional education there are 156 medical schools in the United States, and of this number only thirteen require as much as a high-school course of study for entrance.

We hope that the day is not far distant when all our medical schools will require at least the equivalent of two years' college study for admission to their courses.

Proper Unification of Sanitary Interests in State Work.—The interested observer of public affairs in the various states of the Union can hardly fail to note the diversity of administrative methods that prevail, showing both lack of systematic study in original legislation and lack of proper economic methods in administration. This is especially true in regard to those bureaus or departments which directly or indirectly owe their existence to sanitary reasons. The State Board of Health, the ostensible responsible body in regard to such matters, is in most States shorn of many of the powers that should belong to it and denied proper financial support for the performance of the few duties it is directed to assume. Certain other departments of public administration which exist solely for sanitary reasons are exempt from either control by or co-operation with the State Board of Health, but are lavishly if not extravagantly provided for in the annual appropriations. Dairy commissioners, live-stock boards, mine inspectors, plumbing inspectors, pure-food investigators, State chemists and the like officials of whatever grade or character have no other legitimate claim for existence and public remuneration except the sanitary one. When the offices are created separately, given special power, supported by individual appropriations, they lose their effectiveness, minimize the amount

of work done, increase useless expenditures, become more or less influential political jobs and in the end keep the legitimate Boards of Public Health from receiving the recognition and support which should be given them in the interest of the public.

It has been suggested that future public health legislation shall take cognizance of these administrative abuses that are the outgrowth of our present systems. Proposed laws should in the future provide for unification of the various departments of work specified under the control of the State Boards of Health and their executive officers. One trained inspector at a salary of \$1,000 per year can usually do more work for an active Board of Health than is done by a Dairy or Pure Food Commissioner at a salary of \$3,000 per year with an assistant at \$2,000 per year, a chief clerk at \$1,200 per year and a stenographer at \$75 per month. It is well known that in such office forces as that just described the actual work is usually done by the \$75 a month stenographer, while the other highly paid, inexperienced and inefficient officers spend their time in using up railway passes. Let us strengthen our State Boards everywhere by giving our interest and support to all measures for increasing their powers, broadening the scope of their control and investigations, limiting the employment of nonprofessional persons in positions that require special training and special capability. The best and most economic administration of all matter pertaining to sanitation is only attained when the powers are conferred upon doctors, and expenditures are controlled by them for legitimate purposes.

The Control of Hospitals.—The disagreement which has lately arisen between the Medical Staff and the Board of Management of the National Hospital for the Paralyzed and Epileptic, in London, serves to bring into prominence some of the evils that may arise from the exclusive control of hospitals by laymen. The medical staff of this well-known institution, the reputation of which is entirely due to the reputation of its attending physicians, contend that the administration has become defective, and that this condition is due to the concentration of power in the hands of one official who is not a medical man. The causes of the grievances are found in a defective diet, poor care of the patients, and unsatisfactory nursing. These complaints have been formulated by the staff in a paper drawn up for the enlightenment not only of the Board of Management, but also of the profession and public at large. With their merits we are not here concerned, except to say that, emanating, as they do, from a body of such distinguished and conscientious men, they are deserving of credence. The controversy has reached such an acute stage that the distribution committee of the Hospital Sunday Fund has withheld the customary grant to the hospital pending an adjustment of the difficulty. As hospital managers are keenly sensitive

in their pockets, this discipline may be effective. The attending physicians of the hospital are in the meanwhile agitating for a representative on the Board of Management, and this is the point of general interest to which we draw special attention.

While it might not be practical in all instances, it would doubtless be beneficial in many, to have such a representative on the boards of management of hospitals. These institutions owe their first and greatest obligation to the medical men who serve them. Whatever benefits they confer, and whatever reputation they acquire, are due more to their medical staffs than to all other agencies combined. We say this deliberately, with all due deference to endowments and to lay assistants and coworkers in general. The essential and crowning work of the hospitals is the work done by physicians and surgeons. To promote that work is the very object of the existence of these charities. This is conspicuously but not exceptionally true of the National Hospital for the Paralyzed and Epileptic, for this infirmary has been served and made illustrious by some of the most distinguished of British neurologists. Without their names and labors the hospital would be unknown to fame. These facts demand recognition in all hospitals, for it would seem to go without saying, that no men are so competent to know the needs of a hospital as the members of the profession without whose skill and labor its very existence would be in vain.

Opium in Summer Diarrhea of Children.—Floyd M. Crandall (*International Medical Magazine*, July, 1900) feels that the conclusion that opium should have no part in the treatment of diarrhea in young children is too sweeping and based on a misapprehension. When used to relieve pain, to check peristalsis, to stimulate the heart, and to decrease the secretion of the intestinal tract, particularly in the later stages of the diarrheal attacks, its results are beneficial. It is not indicated when the movements are not large, nor very frequent and are due to septic decomposition; neither should its use be continued when increasing fever gives evidence of increased absorption of toxic matter. It should not be added to the ordinary diarrhea mixture, but should be given alone at intervals of about 4 hours. Lack of precision and accuracy has caused much of the harm resulting from the use of opium in diarrhea. The dose should be as small as possible, and narcotization should be strictly avoided. Paregoric and deodorized tincture are most available for young children. It is contraindicated (1) in the first stages of acute diarrhea, before the intestinal canal has been freed from decomposing matter; (2) when the passages are infrequent or of bad odor; (3) when there is a high temperature or cerebral symptoms are present; (4) when its use is followed by elevation of temperature or the passages become more offensive. It is indicated (1) when the passages are very frequent, with pain; (2) when the passages are excessively frequent, large, and watery; (3) in dysenteric diarrhea preceded by castor oil or a saline; (4) in late stages, with small, frequent, nagging passages; (5) when the passage consist largely of undigested food, and the bowels act as soon as food is taken into the stomach. [M.B.T.]

Correspondence.

THE PHYSIOGNOMY OF CHRONIC PULMONARY TUBERCULOSIS. A CHARACTERISTIC PECULIARITY IN THE APPEARANCE OF THE NOSE.

By HENRY L. SHIVELY, M.D.,

of New York.

Physician to the Presbyterian Hospital Dispensary, Department of Heart and Lungs.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE interest taken by the profession in the minor signs and symptoms of pulmonary tuberculosis, as evidenced by several recent communications in the columns of the PHILADELPHIA MEDICAL JOURNAL, may make the present communication not untimely. In the course of attendance upon a dispensary service in which a large proportion of the cases are consumptives, I have observed the frequency with which in incipient tuberculosis there occurs a pinched nose of peculiar waxy pallor, against which the brownish-yellow orifices of the sebaceous ducts stand out like dots in marked relief. This anemic, dotted nose may be present when there is but

little or no general emaciation or anemia, and so far as I know has not hitherto been described. The appearance is most marked at the tip and lower third of the nose, and in rare instances a similar condition of the chin has been observed. The appearance is not constant, and is less frequently present in subjects of an excessive alcoholic habit, but occurs sufficiently often to be of some diagnostic value. In a number of instances when the patient has not complained of pulmonary symptoms I have been led to make an examination of the chest by the appearance of the nose, and have found the usual physical signs of incipient phthisis. The accompanying sketch may help to give an idea of the appearance described. The importance of an early diagnosis in pulmonary tuberculosis is so great that every slight addition to the symptom-complex cannot but be of value if confirmed.

ACUTE ERGOT POISONING.

By E. S. CLOUTING, M.D.,

of Germantown, Pa.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

As cases of acute poisoning by ergot are rare, and by gallic acid unknown, I wish to record an interesting case occurring in my practice.

A woman, single, 42, feeble-minded, and a victim of pulmonary tuberculosis, had, on June 9, a severe attack of hemoptysis. I saw her during the attack, administered the usual remedies with success, and on leaving ordered 24 ten-grain powders of gallic acid, one to be taken every 2 hours, also 2 ounces Squibb's fluid extract of ergot, directed to be taken in doses of a half-dram every 4 hours till hemorrhage ceased. The following day I called and found the patient sitting up, having taken all the gallic acid and ergot in the night because she was thirsty, her mother having fallen asleep. I waited,—called the following day. I am sorry I did not have her photographed. All over the trunk and face, back of hands, and upon the arms were large irregular, purpuric spots about from one-half inch to 2 inches in diameter, not disappearing upon pressure. The spots were almost running together. The arms and face, especially, looked as if some one had beaten her, but there was no swelling, and her mother told me the eruption came out while the patient was asleep. There was no rise of temperature at all; all functions were normal; no bad feeling existed. The eruption slowly disappeared, but without the effused blood changing color, as in contusion, and in a few days she was as well as before she was taken sick. I attributed the eruption to the ergot (as I have myself taken almost an ounce of gallic acid in 36 hours with no bad result), but acting contrary to the usual physiological action, in one way, as it increased the quantity and frequency of urination; of this I am positive. I gave her a half-grain of calomel every half-hour for 12 doses, and $\frac{1}{30}$ grain of strychnin nitrate, 4 times a day.

As the physiological action of ergot in large doses is the production of depression of the circulation and progressive paralysis of the vasomotor system and the heart, could it be that this was caused by vasomotor paralysis?

ORIENTAL SORE.

By BARTON LISLE WRIGHT, M.D.,

of Mindanao, P. I.

Assistant Surgeon U. S. Navy.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

A SHORT description of this disease may be of interest to those in the United States who are interested in skin diseases, as well as to medical officers of the navy and army, who must now look forward to long tours of duty in the far East, and are therefore likely to encounter it. I therefore make a few general remarks upon its characteristics, and report one case which I have had under observation. For much of the subject-matter, except the personal observations on the case treated, I am greatly indebted to that excellent work, "Tropical Diseases" (Manson).

Oriental sore is a contagious affection of the skin, of parasitic origin, characterized by the appearance of a shotlike, itching papule or papules, which tend to break down, with the formation of a peculiar pinkish, scaly ulcer, of indolent nature. It is endemic in Morocco, the Sahara, Egypt, Crete, Cyprus, Asia Minor, Mesopotamia, Arabia, Persia, Turkistan, and India, where it is quite common and is often locally spoken of as "Bagdad boil" or "Delhi boil," because of its prevalence in these localities. Manson states that "In Bagdad few escape an attack; visitors, even of a few days only, are almost certain, at particular times of the year, to contract it." "In the tropics it is most frequently met at the commencement of the cool season." (Hirsch.) The disease most frequently appears upon the hands, feet, arms, legs, or face; at times on the trunk; but never on the palms, soles, or scalp. The resultant scar, after healing has taken place, is pronounced, especially when considerable surface has been involved. The following case came under my observation:

One of the crew of this ship presented himself with five or six reddish, itching, shot-like papules in the right popliteal space. In from two to three days these were covered with fine grayish-white scales; which, when scraped off, revealed the beginning of ulceration.

The scales reformed, and the ulcers slowly spread, discharging a small amount of ichorous pus, the center being covered by the scales, which assumed a darker color and became more firmly adherent. As the ulcers slowly increased in size they showed a tendency to coalesce. They now began to show signs of healing; but, at the same time, new papules formed both above and below, going through the same process of ulceration. At about the time the original ulcers were fairly skinned over they would break down here and there, giving more or less trouble. This also took place in the later developed areas of ulceration. By this time the whole popliteal space was involved, the disease extending from 3 to 4 inches up the posterior aspect of the thigh, and from 2 to 3 inches down the leg.

The disease developed about April 12 and lasted until June 17, 1900, a period of two months and five days. Six days of this time, May 3 to 9, the patient was relieved from duty.

On April 8, 1900, we first visited Kudat, British North Borneo, and the crew were given liberty. I have no doubt that the disease was contracted at that time.

The treatment given consisted in daily washing of the affected part with a solution of carbolic acid (2%) and applying the following ointment:

R.—Zinc oxid.....	10.0 grams.
Sulphur.....	10.0 grams.
Petrolatum.....	30.0 grams.

M. et ft. ungt.

Later, about the sixth week of the disease, a 10% boracic acid ointment was substituted for the former, and the "four chlorids" given by the mouth three times daily.

It is claimed that one attack renders the patient to a certain degree immune. Second attacks do not often occur. In this connection it is of interest to note that on this date, June 30, 1900, the patient presented himself, displaying similar papules upon the right elbow. Manson, in his "Tropical Diseases," states that the disease is usually of long duration, lasting from two to twelve months, or even longer.

ANESTHESIA BY INJECTION OF COCAIN INTO THE SPINAL CORD.

By GEORGE G. HOPKINS, A.M., M.D.,

of Brooklyn, N. Y.,

Surgeon to St. John's Hospital, etc., etc.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

SINCE the discovery of general anesthesia by the inhalation of ether and chloroform the trend of investigation has been in the direction of some substance less dangerous to life, yet that would suspend both sensation and consciousness. On May 19 last, Professor Tuffier, of Paris, published a report of a method for suspending sensation throughout the entire human system, while the patient retains perfect consciousness. This reduces the risk of anesthesia, as it does not disturb the most vital and important of functions. Dr. Tuffier's method consists in the introduction of a solution of cocain into the spinal canal. In from 4 to 10 minutes from the time of the introduction of the solution, there is perfect and complete anesthesia of the nerves of sensation, throughout the entire system, with slight diminution of the motor powers, but not the slightest effect upon consciousness. At the time of the publication of the monograph mentioned, he had operated in 63 cases, while the patients were rendered insensible to pain by this method. Since that time he has operated on 107 cases while sensation was suspended by cocain injection. It was my privilege on August 2 and 3 to see him operate on the last four of this second series of cases.

The first operation was a gastrotomy. The case was that of a man, 50 years of age, suffering from cancerous obstruction of the pharynx. The mass involved the entire left side of the neck, extending from the superior maxillary articulation to the sternum, dipping back to the spine and including all the vessels and muscles of that side of the neck. The patient was anemic and greatly emaciated. Observing asepsis and antisepsis, the needle was introduced between the fourth and fifth lumbar vertebrae. The patient was placed upon the operating table, and the assistant prepared the site of operation. In 10 minutes M. Tuffier began his incision for gastrotomy. The man was interrogated from time to time during the operation, which lasted about 35 minutes, and said that he had not the slightest sensation of pain, and his eyes being covered, he could not tell where the operator was cutting. The pulse was slightly accelerated and the patient had some nausea, but it was of a passive kind; there was no retching.

The second operation was for the radical cure of inguinal hernia. The patient was a man, 30 years of age, in fine physical condition—a magnificent specimen of muscular development. The injection was made in the same region, and with the same precautions. In 10 minutes insensibility was complete. M. Tuffier operated with great deliberation, consuming about 25 minutes. The patient said he had not the slightest sensation of pain, and certainly did not in any way indicate that he suffered. He said he could not tell by his feelings whether the surgeon was operating upon his abdomen or his arm. He had no nausea.

The third operation was for the removal of a bullet, lodged in the femur near the knee-joint. It had entered about the middle of the thigh and passed downward. This man was 25 years of age, and a strong, healthy subject. The cocain injection was made in the same region, and with the same precaution as in the other cases. The patient experienced no pain during the operation. The cut was a longer one, and the search very thorough. This patient had nausea.

The next operation, on the day following, was an abdominal hysterectomy. The patient was a small, spare woman, about 40 years of age, and was evidently a great sufferer. The injection in this case was made with the same care as in the other cases. This operation took 70 minutes, as there were extensive adhesions, and both ovaries were cystic and had to be removed before the uterus could be reached. This patient had considerable nausea of a passive kind. She said that she did not experience any pain, and had no sensation that would indicate to her where the operation was being done.

Such are the results of this remarkable procedure. M. Tuffier uses a long platinum needle built according to his direction. The syringe is much larger than the ordinary hypodermic syringe. He uses a 2% solution of cocain, and places great stress on the preparation and sterilization of the solution before it is injected. A description of the process would be somewhat long for insertion here. The main point is to be sure that the solution is sterile. It should always be made fresh for each operation, or at least not kept longer than 48 hours.

The dose of cocain should never exceed 2 cgm.; usually it should not exceed 1.5 cgm. Perfect insensibility to pain will ensue in from 4 to 10 minutes and continue for 1½ to 2 hours after the injection has been made. Sensation returns first in the pharynx.

Of the 63 cases which M. Tuffier has reported, nausea was present in 50 cases. There was an increase in temperature in 15 of these cases during the first 12 hours; after that it was normal. The pupils are usually dilated; the pulse-rate slightly increased. In 4 cases there was a chill with trembling, lasting from 10 to 15 minutes, but not followed by fever.

M. Tuffier was very cautious in his procedure. His first operations were of minor surgery, working up gradually to abdominal sections and all major operations. His last 107 unpublished operations all were important. He has never

yet had an accident from the use of the cocain. In two cases, when he used a solution of cocain that had been kept for some time, anesthesia was not perfect and he had to resort to ether-inhalation. But since he has been careful to use only a fresh solution, insensibility to pain has always been complete in ten minutes at most, and remained complete for from 1½ to 2 hours. Ether-inhalation after the cocain-injection is not contraindicated.

The ages of his patients have varied from 12 to 63 years. He considers it unsafe to make the injection in young children.

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Board of Charities.—Dr. Ellwood R. Kirby has been appointed a member of the Department of Charities and Correction of Philadelphia, to succeed Dr. Gairdner, deceased.

Christian Science Again.—The Coroner of Philadelphia is investigating the death of Giles J. Burgess, who died of tuberculosis after six months' treatment by a Christian Scientist.

Disease Breeding Nuisance Abated.—Recently 6 traders near Thirtieth and Market streets, Philadelphia, were arrested and fined for throwing decayed and refuse matter in the gutters.

Bequest to Wills Eye Hospital.—By the will of the late George W. Gross, of Lower Merion, Pa., all his estate, after the payment of a few small bequests, will revert to the Wills Eye Hospital, of Philadelphia.

Woman's Medical College of Philadelphia.—Dr. W. L. Rodman has recently been appointed professor of the principles and practice of surgery, and Dr. W. V. Laws, professor of operative and clinical surgery.

Leeches in His Ear.—A boy at Lancaster, Pa., had 2 leeches removed from his ear recently by a physician. He had been bathing and for 3 days following suffered from severe earache, and was almost on the verge of convulsions when the removal afforded instant relief.

Cholera Day in Pittsburg.—Over half a century ago the members of St. Michael's Roman Catholic Church in Pittsburg, Pa., made a vow that if they were freed from the ravages of cholera, then claiming hundreds of victims in that city, they would annually hold appropriate services. On August 21, fully 5,000 persons were present in the chapel of the church at different times.

Faith Curists Arrested.—Rev. Charles F. Newell, Mrs. C. S. Boyd, and Mrs. Louise Elhart were arrested at Scranton, Pa., recently on information furnished by the Coroner, who charged them with involuntary manslaughter in causing the death of Mr. Newell's wife after childbirth. The parties are believers in the Dowie faith, the doctrines of which are antagonistic to medical treatment.

For Charity.—By the will of Michael Corr of Philadelphia over \$30,000 will be distributed among 23 Catholic institutions and churches in and about the city, in sums varying from \$1,000 to \$10,000. Archbishop Ryan and the Rev. J. Fitzmaurice are each given \$10,000, to be used for charity as they may see fit. After the death of Corr's relatives the money left in trust for them will revert to charity.

Public Baths and Conjunctivitis.—The Philadelphia Health Department has been notified that at 2 hospitals the cause of the unusual prevalence of conjunctivitis has been traced to public baths. At St. Christopher's Hospital about 200 cases have been treated during the last 3 weeks, and almost as many at the Pennsylvania Hospital. The complaint has been investigated by medical inspectors, and they claim that the 9 baths maintained by the city are

in a very satisfactory condition. Fresh water is constantly flowing from the city mains into these pools, and each pool is emptied and flushed with a fire hose 3 times a week and disinfected. In addition to this, every known precaution is taken by the superintendents to prevent persons who are suffering with a skin disease of any character from entering the baths.

Vital Statistics of Philadelphia for the week ended August 25, 1900:

Disease.	Cases.	Deaths.
Total mortality		372
Inflammation of appendix 3, brain 13, bronchi 2, kidneys 17, lungs 15, peritoneum 2, pleura 1, stomach and bowels 16, heart 2		71
Debility 7, marasmus 23, inanition 23		53
Tuberculosis of lungs		37
Cholera infantum 26, morbus 1		27
Bright's disease 8, uremia 8, diabetes 2		18
Heart—disease of 16, fatty degeneration of 1, neuralgia of 1		18
Apoplexy 9, paralysis 7		16
Convulsions 12, puerperal 1		13
Old age		12
Typhoid fever	61	9
Diphtheria	37	9
Casualties		8
Carcinoma of stomach 2, liver 2, neck 1, rectum 1, uterus 1		7
Stroke		5
Whooping-cough		5
Suicide—hanging 2, shooting 1, drowning 1		4
Cirrhosis of liver		4
Burns and scalds		3
Aneurysm of aorta		3
Cyanosis		3
Scarlet fever	18	3
Diarrhea 2, dysentery 1		3
Intussusception of bowels		3
Surgical shock		3
Septicemia		3
Abscess of pelvis 1, alcoholism 2, asthma 1, anemia 2, congestion of brain 1, drowned 1, abdominal dropsy 1, epilepsy 1, malaria 2, hernia 1, homicide 1, insanity 1, jaundice 2, measles 2, obstruction of bowels 1, edema 1, poisoning—laudanum 1, opium 1, pyemia 1, rheumatism 2, scrofula 1, teething 2, tetanus 1		3

Lehigh Valley Medical Association and the Berks County Medical Society.—A joint meeting was held at the Neversink Mountain Hotel, Reading, Pa., August 16, 1900, it being the summer meeting of the former and the annual outing of the latter. Dr. J. MILTON DUFF, of Pittsburg, presented a paper on **Modern obstetrics**. He reviewed the field of obstetrics from its earlier history to the present time. The care of the pregnant woman then and now. Then no care, now she should be seen by her attending physicians every few weeks during pregnancy. See that she has as nearly as can be the proper environment. Examine her urine often, so as to notice early should there be any abnormal change in the secretion of urine. Her blood should also be examined several times, as no woman can have a healthy child whose blood is not in a healthy state. The position of the child should be ascertained as early as possible by external palpation. The pelvis should be measured so as to ascertain the size, and whether the parts are sufficiently large and yielding, so as to permit of passage through the bony structure, as well as through the vaginal canal. Aseptic obstetrics has saved as many lives during labor as aseptic conditions in surgery. The **preparation of the parturient woman** should be the same as for a vaginal hysterectomy, soap, water, douching the vaginal canal with bichlorid of mercury, 1:5000. **During parturition** the Kelly pad and aseptic or sterilized pads, instead of as earlier, old and cast-off clothing that were not always clean, and never sterilized. The hands of the attendant should be scrupulously clean, the nails never in mourning. **Forceps** should be applied only to relieve the woman, or to save the life of the child, and never to save time for the doctor. **Anesthesia**, he said, was a great boon for the parturient woman. It calms her nervous system, relaxes the rigidity of the parts, relieves her of much of the acute suffering, and saves much of her vitality. The physician should at no time be in a hurry to leave the house immediately after labor. If the attending physician can not

give the patient the proper amount of time he should not undertake the case. After making a vaginal examination, and finding all conditions relating to a normal labor, wait and watch for developments, instead of making many examinations at frequent intervals. **Midwives** were condemned in general. **Saving the mother and child during labor.** Some teachers say always save the mother if only one can be saved. Dr. Duff says "save both," as the operation for cesarean section is readily done, and the death-rate when done early is very low, either to the mother or child. **District nursing.** As the price for professional nursing is above what many poor persons can pay, he advised churches or other organizations to raise a fund so as to pay for district nursing, and thus save many lives of women and children. Mortality in the modern hospital is less than $\frac{1}{2}\%$, whilst in general obstetric practice outside of a hospital it was at least 4%. Dr. HALBERSTAT, of Pottsville, in opening the discussion, said modern obstetrics was not due to the results of investigations of the obstetrician, but was due to the bacteriologist in the laboratory. First cleanliness, avoid meddling. The forceps were a "godsend" to the parturient woman, when properly used. Dr. P. A. HARRIS, of Paterson, N. J., delivered the annual address before the Lehigh Valley Medical Society upon the subject of **Certain pathological conditions of the fallopian tubes of interest to the general practitioner.**

NEW YORK.

New Hospital at Saratoga.—A new hospital was recently opened at St. Christina's Home, Saratoga, N. Y.

Chapin Home.—By the will of the late C. P. Huntington the Chapin Home for the Aged and Infirm of New York will receive \$25,000.

Sulfonal Causes Death.—Almon W. Sargent died recently at Watertown, N. Y., from the effects of an overdose of sulfonal. To produce sleep he took 440 grains 75 hours before his death, and never woke up.

Fleas and Red Ants.—The south side of Long Island has become the prey of pestiferous fleas and red ants. Their bite is painful, and physicians have been unable to do much for the sufferers, who depend upon home remedies.

Milk Trust.—A charter has been granted recently to the Century Milk Company, of New Jersey, said to be a combination of the big milk dealers of New York and vicinity. The new company has an authorized capitalization of \$1,000,000.

Geneva City Hospital.—By the will of Judge Francis O. Mason, of Geneva, N. Y., the Geneva City Hospital is to receive \$100,000. Of this amount \$10,000 is immediately available, and the remainder at the death of 2 sisters of the deceased.

Kneipp Cure Failed.—A patient came into Bellevue hospital recently and said that while at Monroe he had joined a colony of Kneipp curists. To cure his corns he walked about in his bare feet for several successive mornings until his feet became so swollen as to cause him much alarm. The Bellevue doctors said he was suffering from ivy poisoning.

Sanitation in New York.—Dr. John B. Cosby, one of the Health Commissioners of New York, who has been traveling in Europe for some time, says the hygienic conditions of New York are unexcelled by any other city of considerable size in the world. Whether this is due to the natural advantages of the tide-swept shores or the natural habits of the American people is hard to determine.

Serum that Cures Rattlesnake Bite.—For Dr. Louis de Plasse, of New York, is claimed the honor of establishing in this country the efficacy of Dr. Calmette's serum as a cure for the bite of a rattlesnake. He injected 10 cc. of serum into his dog that had been bitten and was about to die. The animal promptly recovered. Dr. de Plasse states that the injection of 10 cc. of the serum is sufficient for either children or adults in the case of bites of either rattlesnake, copperhead or pilot snake. He says the serum contains no poison and can be injected with perfect safety.

Conference of Deaf-mutes at Syracuse.—The twenty-first annual conference of the Empire State Association of Deaf-Mutes was held in Syracuse, N. Y., last week. The majority of the delegates are bright business men. They use the sign language. President Thomas F. Fox, head teacher of the New York State Institution for Deaf-Mutes, in his address, made an appeal for the Gallaudet Home for Aged and Infirm Deaf-Mutes at Poughkeepsie.

Argon.—New York physicians are experimenting with argon to ascertain its uses as a cure for various diseases. Dr. C. W. Fitch, former surgeon in the United States army, says it is a mystery, but the cures already made have been wonderful. He hazards the opinion that argon acts upon or through the nervous tissue which governs the process of repair, and indirectly, possibly, through the glandular system as well. It awakens sluggish nature to new activity.

NEW ENGLAND.

City Physician of Lynn.—Dr. George C. Carr has been elected city physician for the westerly district of Lynn, Mass.

Woman City Chemist.—Miss Marion Cowan, of Lynn, Mass., was recently elected chemist for the board of health of that city. She is the only woman chemist in New England to act in the capacity for which she was chosen.

Chelsea Hospital.—Improvements, for which the government has appropriated \$45,000, are being made at the United States Naval Hospital at Chelsea, Mass. Larger buildings are to be provided, and plumbing and ventilation regulated.

Athlete Victim of Tuberculosis.—George Hosmer, who was at one time the leading oarsman of the world, died of tuberculosis in a Boston hospital. His professional training may have not been directly responsible for his death, but he is one of a long list of athletes who, after posing as marvels of muscular development, have slowly wasted away from tuberculosis. The strain of physical training is severe in most cases, and professional athletes must be careful as to their habits if they would ward off collapse.

CHICAGO AND WESTERN STATES.

Hospital Ordinance a Law.—The new City Hospital ordinance of St. Louis recently became a law, and plans for constructing the building are being drawn.

Physician Held for Assault.—Dr. W. D. Turner, of Pasadena, Cal., is in the custody of the police awaiting the outcome of the injuries inflicted on Daniel J. Carroll.

Asks \$10,000 for an Eye.—Benjamin Hesse, of Fort Madison, Iowa, has filed a claim for \$10,000 against John E. Hinze for the loss of an eye, caused by a blow.

University of Chicago.—Dr. Lewellys F. Barker, formerly associate professor of anatomy in Johns Hopkins University, has been made professor of anatomy at the University of Chicago.

Poisoned by Milk.—Near Wausaukee, Wis., 5 persons were poisoned by drinking milk. The nausea and vomiting were severe when the physician arrived. An analysis of the milk showed a development of ptomaines.

Emergency Hospital for the Chicago Stockyards.—A movement is on foot to provide an emergency hospital near to the packing houses and railroads where accidents are of daily occurrence. The nearest hospital to the Chicago stockyards is 5 miles distant.

The San Francisco Board of Health have appointed 2 food inspectors. They have also adopted an ordinance intended to regulate the maintenance of slaughter and packing houses and to prevent the sale of watercress and other edible vegetables growing near cesspools or on lands into which any sewage or impure matter is emptied. Plans for the new Nurses' Home at the City and County Hospital, to cost \$2,000, have been filed and referred to the hospital committee.

Physician Injured.—Dr. W. R. Patton, Mayor of Charleston, Ill., while making a professional call, was thrown from his buggy and probably fatally hurt. His injuries are of an internal character, and attending physicians say his recovery is doubtful. He is serving his fourth term as mayor.

Thought to be Glanders.—Recently, several members of a family near Wautoma, Wis., have broken out with a strange disease which has puzzled a number of physicians. Some time ago, the horses of the family were afflicted with glanders, and they think there is some connection between the diseases.

The Washington State Medical Society is made defendant in a suit begun by E. J. Lake. Plaintiff alleges that he was engaged to report the proceedings of a meeting of the society, held in Spokane, and that repeated demands for payment have been refused by the officers of the society, hence the suit.

A Real Globe Trotter.—Dr. LeCluyse, who is making a tour of the world on foot, will be in Milwaukee, Wis., soon. He travels at the rate of 45 miles a day, and has been on the road 20 months, starting from his home in Brussels, Belgium. He is a graduate of the University of Belgium, and because of insomnia has taken to walking.

Unlicensed Physicians.—Dr. L. C. McElwee, secretary of the Missouri State Board of Health, conferred with Assistant Prosecuting Attorney R. M. Johnson recently with regard to the prosecution of physicians who are practising without licenses. Dr. McElwee said there are 5 prominent physicians in St. Louis who had not complied with the law. Warrants will be issued if the proper evidence is submitted.

Nail Driven into Brain.—Dr. Emil Enos, chief of the medical staff at Kankakee Insane Asylum, Ill., has prepared for the coming meeting of the American Association of Hospital Physicians, at Indianapolis, skiagraphs and data of a strange case under his care. The patient is Miss Elizabeth Sharp, of Bloomington, Ill., who has fully recovered physically, after driving the full length of a nail into her brain. The nail was removed with forceps. She used the heel of her shoe as a hammer, and says she felt no pain. Dr. Enos says the nail would certainly have killed her had she not been insane.

SOUTHERN STATES.

Hospital Buildings at Salisbury, Md.—Plans and specifications for a hospital at Salisbury, Md., have been completed and bids for erection invited.

Hospital Needed at Annapolis.—The Health Officer of Annapolis suggests the great need of a hospital in that city. The hospitals of Washington or Baltimore are the only recourse when an accident occurs.

Home for Tuberculous Individuals.—A plan is in operation to build a home at Asheville, N. C., for persons suffering from tuberculosis. A large farm has been purchased and an opportunity will be given the poorer classes to work for their board.

Pure Water at Cumberland.—For the first time in 8 years the water of the Potomac, near Cumberland, Md., from which the city is supplied is clear and odorless, as the result of the closing down of the pulp mill at Luke. Fish driven down by the pollution are again coming up and are being caught near the city. The shut-down at the pulp mill is due to the substitution of the soda for the sulfite process, which is now in progress. The new process is harmless to running water.

Charity Gets \$316,000.—By the will of the late Mrs. Margaret J. Bennett, of Baltimore, the following bequests have been made: \$150,000 for the purpose of founding the Margaret J. Bennett Home for Homeless, Needy, and Deserving Females; \$25,000 to the Woman's College of Baltimore for founding 6 scholarships; \$25,000 to the Hospital for the Women of Maryland; \$25,000 to the Home for the Aged of the Methodist Episcopal Church; \$5,000 to the Free Summer Excursion Society; \$2,000 to the Nursery and

Child's Hospital; \$2,000 to the Kelso Home for Orphans; \$1,000 to the Asylum and Training School for the Feeble-Minded of the State of Maryland; \$1,000 to the Little Sisters of the Poor; and \$1,000 to the Home for Incurables.

MISCELLANY.

The Maine at Hongkong.—Advices from Hongkong report that the American hospital ship *Maine*, which sailed from Southampton for China on July 12, arrived there August 25.

Mortality at Nome.—Since June 1 the coroner's records at Nome, Alaska, show 71 deaths, of which 29 were natives. Only one death from smallpox is recorded, most of the deaths being from pneumonia. In all, 20 cases of smallpox have been admitted to the hospital.

Epidemic in Managua.—An epidemic is causing the death of rats and pigs in Managua, Nicaragua. The number of pigs that have died from the unknown malady is very large. The Sanitary Commission is endeavoring to prevent the outbreak of a possible epidemic among the population.

Red Cross Work for India.—The American National Red Cross announces that under the powers conferred upon it by the last Congress it will at once begin active work for the relief of those suffering from famine in India. Headquarters for this branch of relief will be opened in New York.

Smallpox from Nome.—A steamer from Nome to Seattle recently put into Dutch Harbor, Alaska, with a case of smallpox on board. The patient was isolated on Hog Island. The *Gayhead* arrived later with several cases on board. A Marine-Hospital surgeon has taken charge of the quarantine station at Hog Island.

Physician Sues Queen Lil.—Dr. Charles E. English, of Honolulu, Queen Lil's private physician for over 2 years, has sued her for over \$5,000. He declares he gave up all his practice to attend her, for which he received \$300 a month, with a bonus of \$5,000 should she part with his services. In case she received compensation for crown lands he was to get \$30,000. In July, he claims, she suddenly dropped him and refused to pay the bonus.

Hospital Accommodations Good.—Surgeon-General Sternberg received the following from Major H. O. Perley, Surgeon United States Army, in command of the hospital ship *Relief*: "Taku, August 23.—Have 50 wounded on *Relief*. More coming. Hospital accommodations are excellent Tientsin. Launches and boats from *Relief* bringing wounded from Tientsin. Have everything needed. All well cared for; will look after everything here."

Dentistry and Veterinary Surgery.—It is reported that schools of veterinary surgery have added dentistry to the curriculum. A dentist not long since operated upon a monkey that had toothache; and a sheep-farmer in South Wales has had artificial teeth made for a valuable ram that, owing to the loss of his natural grinders, could not masticate his food. A full set was supplied, and it is said the animal at once attacked his fodder with relish.

International Hospital Courtesies.—Count von Solms, the Imperial Commissioner for Voluntary Sanitary Work in China, wrote to the Secretary of the United States Embassy at Berlin, recently, thanking him for the offer of the American hospital ship *Maine* to accommodate the German wounded and sick in China. In return, Count von Solms tendered the use of all the German hospital facilities there to the United States Army and Navy.

Obituary.—WILLIAM B. WATERMAN, of Brooklyn, August 21, aged 38.—SAMUEL A. KENNEDY, of Shelbyville, Ind., August 22, aged 65.—JOHN D. MCAULIFF, of St. Louis, August 23, aged 77.—MOSES WARREN KIDDER, of Lincoln, Mass., August 15, aged 72.—BENSON BOND, of St. Joseph, Mo., August 24, aged 71.—J. P. EGOMANN, of St. Louis, August 25, aged 31.—FRANCIS FENWICK SMITH, of Frederick, Md., August 26, aged 72.—W. H. MUSGROVE, of Grafton, N. D., August 8.—E. W. BEEBE, of Elizabeth, Ill., August 26, aged 72.—ERNST SCHMIDT, of Chicago, August 26, aged 70.—JAMES H. MAC-

CORMAC, of Poughkeepsie, N. Y., August 25, aged 56.—FERDINAND E. CHATARD, of Baltimore, at Atlantic City, August 27, aged 61.

Alcohol for the Navy and Tartar Emetic.—Captain C. D. Sigsbee, of the U. S. Navy, recently made a proposition to the Navy Department. He says that the presence of alcohol, even wood alcohol, used on board ship for paints, varnishes, etc., leads to considerable drunkenness; that there are among the crew those who know how to abstract the alcohol from mixed shellac and to clarify it even when the shellac has been mixed with veretian red. Captain Sigsbee recommends that an order be issued requiring that all alcohol used in the construction department of ships be mixed with a certain amount of tartar emetic, and that the cases, chests or bottles in which the alcohol is kept shall be marked accordingly. The bureau did not approve of the suggestion.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended August 23, 1900:

Changes in the Medical Corps of the U. S. Army for the two weeks ended August 25, 1900:

MOSELEY, Major EDWARD B., surgeon, is relieved from the command of the Second Reserve Hospital, Manila, P. I., and will report to the commanding general, department of Southern Luzon, for duty as chief surgeon of that department, relieving Major Junius L. Powell, surgeon, who will report to the chief surgeon of the division for instructions.

POWELL, Major JUNIUS, surgeon, will report to the commanding general, department of Northern Luzon, for temporary duty in that department.

BECKMAN, PETER W., acting assistant surgeon, will be relieved from temporary duty at the Presidio in time to enable him to report on the transport "Aztec," for temporary duty during the voyage of that vessel.

CHASE, ALPHA M., acting assistant surgeon, will be relieved from temporary duty at the Presidio in time to enable him to report on the transport "Strathgyle," for temporary duty during the voyage of that vessel.

SMITH, ARTHUR B., acting assistant surgeon, will proceed from San Francisco to the U. S., General Hospital, Fort Bayard, for temporary duty.

WRIGHT, Colonel JOSEPH P., assistant surgeon-general, is granted leave for 4 months, from August 25.

DICKER, Major ORLANDO, surgeon, orders which direct him to proceed to San Francisco, Cal., and report to the commanding general, department of California, for duty, are so amended as to direct him upon the expiration of his present leave to report by letter to the Surgeon-General of the Army for instructions.

TRUBY, First Lieutenant ALBERT E., assistant surgeon, is relieved from duty in the department of Western Cuba, to take effect from August 2, and from further duty with the First Infantry, to take effect upon the expiration of the leave granted him by the commanding officer, Third Battalion, of that regiment.

TRUBY, First Lieutenant ALBERT E., assistant surgeon, is granted leave for 20 days, and upon the expiration thereof will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

SCHUYLER, WILFRID H., hospital steward, Fort Sherman, is transferred to Fort Wright for duty, to relieve Hospital Steward Revello M. Walker.

WALKER, REVELLO M., hospital steward, will be sent to San Francisco, Cal., for transportation to China, for assignment to duty.

MENAGE, HENRY E., acting assistant surgeon, now at New Orleans, La., will proceed to Denver, Col., for assignment to duty at Fort Logan.

SMITH, BAT, acting assistant surgeon, now at Fort Sheridan, will proceed to Wharton, Tex., and report by letter to the Surgeon-General of the Army for annulment of his contract.

STONE, First Lieutenant J. HAMILTON, assistant surgeon, is relieved from further duty at Santa Clara Barracks, and will report at Hamilton Barracks, Matanzas, for duty.

FIELD, P. C., acting assistant surgeon, is granted leave for 1 month, with permission to leave the limits of the division of Cuba.

VERANES, FELIFE, acting assistant surgeon, is granted leave for 1 month.

HOFF, Major JOHN VAN R., surgeon, will proceed to Taku, China, and report to Major-General Adna R. Chaffee, commanding the United States forces in China, for assignment to duty as chief surgeon on his staff.

HARVEY, Major PHILIP F., surgeon, will proceed from the Presidio to Nagasaki, Japan, for the purpose of establishing a base hospital at that place.

GEMMILL, HARRY C., acting assistant surgeon, is relieved from duty at Fort Thomas, and will report at that post for duty to accompany the Second Infantry, under orders for foreign service.

COMBES, Major EDWARD T., surgeon, now in San Francisco, Cal., will proceed to Nagasaki, Japan, for duty as medical supply officer at that place.

RICHARDS, First Lieutenant WM. E., assistant surgeon, is relieved from further duty in the department of Puerto Rico, and will proceed to Plattsburg Barracks for duty.

ALEXANDER, JAMES A., acting assistant surgeon, is granted leave for 10 days, from August 14.

DE POORTER, LIVEN, acting assistant surgeon, now in New York City, will upon the expiration of his present leave, proceed to New Orleans and report by letter to the Surgeon-General of the Army for annulment of his contract.

MCCOXTATHY, HERBERT M., acting assistant surgeon, now in Washington, D. C., is relieved from duty in the department of Puerto Rico, and will report at Washington Barracks for assignment to duty with Battery M, Seventh Artillery, en route to San Francisco, Cal., for foreign service.

BENNETT, IRVIN E., acting assistant surgeon, now in Washington, D. C., is relieved from duty in the department of Puerto Rico, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

BROOKS, JOHN D., acting assistant surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

CHAUB, L. D'AVILLE, acting assistant surgeon, will proceed from Youngstown, O., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

CONDON, WILLIAM J., acting assistant surgeon, will proceed from Jamesburg, N. J., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

COSSITT, HARRY A., acting assistant surgeon, will proceed from Morris Plains, N. J., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

DEATON, U. S. GRANT, acting assistant surgeon, will proceed from Thackeray, O., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

DEWITT, WALLACE, acting assistant surgeon, will proceed from Hampton, Va., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

HENDERSON, A. BRUCE, acting assistant surgeon, will proceed from Batavia, Mich., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

KELLOGG, WILLIAM V., acting assistant surgeon, will proceed from Detroit, Mich., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

LEWIS, HOWARD D., acting assistant surgeon, will proceed from Baltimore, Md., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

MARBE, JAMES I., acting assistant surgeon, will proceed from Rockwood, Mich., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

MACY, ROBERT C., acting assistant surgeon, will proceed from Mobile, Ala., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

PATTERSON, EDWIN W., acting assistant surgeon, will proceed from Washington, D. C., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

PERKINS, LOUIS J., acting assistant surgeon, will proceed from Pendleton, Oreg., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

PRESTON, WILLARD D., acting assistant surgeon, will proceed from Attica, N. Y., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

RUTLEDGE, JAMES C., acting assistant surgeon, will proceed from Detroit, Mich., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

SNYDER, CALVIN D., acting assistant surgeon, will proceed from Baltimore, Md., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

BROWN, Major IAA C., surgeon, leave granted to him is extended 20 days.

TRUBY, First Lieutenant ALBERT E., assistant surgeon, is granted leave for 20 days, from August 17, and upon expiration thereof will proceed from New York City to Havana, Cuba, and report to the commanding general, division of Cuba, for assignment to duty.

RICHARDS, First Lieutenant WILLIAM E., assistant surgeon, the acting assistant surgeons and the members of the hospital corps, U. S. Army, who arrived in New York harbor on August 11 on the transport "Sedgwick," from Puerto Rico, will report to the commanding officer, Fort Columbus, for temporary duty pending disposition.

The following changes in stations and duties of officers are announced: Major FREDERICK J. COMBE, surgeon, is relieved from duty in the department of Mindanao and Jolo, and will report to the commanding general, department of the Visayas, for assignment to duty; First Lieutenants JAMES S. WILSON and CLYDE S. FORD, assistant surgeon, are relieved from duty in the department of Northern Luzon, and will report to the commanding officers, Fourteenth Infantry and Twentieth Infantry, respectively, for duty with those regiments, relieving First Lieutenants EDWARD R. SCHREINER and BASIL H. DUTCHER, who will report to the commanding general, department of Northern Luzon, for assignment to duty; Contract Surgeon WILLIAM J. ENDERS will report to the commanding general, department of the Visayas, for assignment to duty; Contract Surgeon WILLIAM R. DAVIS will be relieved from duty in the department of the Visayas, and will report to the chief surgeon of the division for transfer to the United States for annulment of contract.

The following named medical officers will accompany the Second Battalion of the First Infantry and the Light Battery of the Second Artillery to the United States on the Government transport "Crook": With Second Battalion, First Infantry: Acting Assistant Surgeons J. F. DUNSHINE and A. A. NOEL. With Light Battery F, Second Artillery: Acting Assistant Surgeon J. F. PRESNELL. Upon arrival in the United States, and when their services are no longer required with the troops they accompanied, the medical officers will report by letter to the Surgeon-General of the Army for further orders.

GIBSON, Major ROBERT J., surgeon, having reported at San Francisco, Cal., is assigned to duty as attending surgeon and medical superintendent of the Army transport service and as sanitary inspector of the department of California to relieve Major Wm. H. Arthur, surgeon.

AARHUS, Major Wm. H., surgeon, will take station in San Francisco, awaiting transportation to Taku, China.

WADHAM, S. H., acting assistant surgeon, now at San Juan, P. R., on leave, will appear before the medical examining board in session at San Juan, and upon completion of examination will return to his proper station.

SHAW, HERBERT C., acting assistant surgeon, is relieved from duty at the Army General Hospital, Presidio, and assigned to tempo-

rary duty on the Army transport "Sherman," to relieve Acting Assistant Surgeon Henry H. Bradley.

BRADLEY, HENRY H., acting assistant surgeon, will proceed to Camp Osborne, Idaho, for temporary duty at the camp during the absence on leave of Acting Assistant Surgeon J. P. Truax.

CUTLIFFE, WILLIAM O., acting assistant surgeon, is granted leave for 2 months with permission to visit the United States, to take effect upon the arrival of First Lieutenant F. F. Russell, assistant surgeon, at Mayaguez.

SCHULTZE, ERNEST C., acting assistant surgeon, is assigned to temporary duty with troops on the Army transport "Warren," to sail about August 16. Upon arrival at Taku, China, Surgeon Schultze will report to the commanding general, U. S. forces in China, for assignment to duty.

REBART, M. A., acting assistant surgeon, is granted leave for 1 month on account of sickness.

POWELL, DWIGHT C., acting assistant surgeon, now at Logansport, Ind., will proceed to Fort Thomas and report for duty with the Battalion of the Second Infantry, under orders for foreign service.

TAYLOR, DWIGHT B., acting assistant surgeon, will proceed from Columbus Barracks to Fort Thomas, arriving at the latter post not later than August 19, and report for duty to accompany troops to San Francisco, Cal., and upon the completion of this duty will return to his proper station.

TANNER, W. I., acting assistant surgeon, is granted leave for 1 month.

MILLEN, DANIEL, hospital steward, now at Washington, D. C., having relinquished the unexpired portion of furlough granted him from Fort Sam Houston, will be sent to Fort Wingate and report for duty.

GODFREY, Captain GUY C. M., assistant surgeon, the operation of par. 25, S. O. 185, August 8, H. Q. A., relating to him is suspended until further orders.

RAYNOR, WILLIS J., acting assistant surgeon, will proceed from Denver, Col., to Fort Washakie for duty, to relieve Acting Assistant Surgeon Alfred C. Godfrey.

GODFREY, ALFRED C., acting assistant surgeon, will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

NOEL, AUGUSTE A., acting assistant surgeon, now at Fort Leavenworth, will proceed to New York City, and report by letter to the Surgeon-General of the Army for annulment of his contract.

MENAGE, HENRY E., acting assistant surgeon, now at New Orleans, La., will proceed to Fort Wingate for duty to relieve Acting Assistant Surgeon Charles B. Nichols.

NICHOLS, CHARLES B., acting assistant surgeon, will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

HACK, CHAS. W., acting assistant surgeon, is relieved from further duty in the department of Dakota, and will proceed to Columbus Barracks for duty.

CASS, Wm. E., acting assistant surgeon, will proceed from St. Louis, Mo., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

CLAYTON, GEORGE R., acting assistant surgeon, will proceed from Nevada, Iowa, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

FLETCHER, PAUL R., acting assistant surgeon, will proceed from St. Louis, Mo., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

LEWIS, FREDERICK A., acting assistant surgeon, will proceed from Walworth, N. Y., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

MILLER, R. BOYD, acting assistant surgeon, will proceed from Millington, Ill., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

MILLER, THOMAS F., acting assistant surgeon, will proceed from Lamar, Mo., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

MINTZER, GEORGE S., acting assistant surgeon, will proceed from Philadelphia, Pa., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

RAABRETT, JAMES A., acting assistant surgeon, will proceed from Elkins, W. Va., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

RENN, GEORGE A., acting assistant surgeon, will proceed from Raleigh, N. C., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

SEARS, C. EDWARD, acting assistant surgeon, will proceed from Salem, Va., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

HADLEY, JACOB F., assistant surgeon, will proceed from Passaic, N. J., to San Francisco, Cal., and report to the commanding gen-

eral, department of California, for assignment to duty with troops destined for foreign service.

HOGUE, GUSTAVUS I., assistant surgeon, will proceed from North Lake, Wis., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

SANBORN, CHARLES F., assistant surgeon, will proceed from Willard, N. Y., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

SILER, JOSEPH F., assistant surgeon, will proceed from New York City to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

WHEELER, LEWIS H., assistant surgeon, will proceed from Westport, Conn., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

WICKLINE, WM. A., assistant surgeon, will proceed from Warm Springs, Mont., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

PROBERT, MERTON A., acting assistant surgeon, will proceed from Constantia, Ohio, to Columbus Barracks for temporary duty.

PAESNELI, JAMES F., acting assistant surgeon, now at Fort Leavenworth, will report to the commanding officer of that post for duty with the First U. S. Infantry under orders for foreign service.

RICHARDS, First Lieutenant WILLIAM E., assistant surgeon, is relieved from duty at Plattsburg Barracks, to take effect upon the arrival at that post of Acting Assistant Surgeon David J. Johnson, and will proceed to Fort Ontario for duty to relieve Acting Assistant Surgeon George M. Bradfield.

BRADFIELD, GEORGE M., acting assistant surgeon, will proceed to Philadelphia, Pa., and report by letter to the Surgeon-General of the Army for annulment of his contract.

SHAW, Captain HENRY A., assistant surgeon, is relieved from further duty at the U. S. General Hospital, Presidio, and will proceed to Nagasaki, Japan, and report to Major Philip F. Harvey, surgeon, for duty at the U. S. General Hospital to be established at that place.

HIGGINS, AUBREY F., acting assistant surgeon, is relieved from duty in the department of California, and will report to the commanding general of that department for assignment to duty with troops destined for the Philippine Islands.

SAUNDERS, HERBERT F., acting assistant surgeon, will proceed from Greenville, Ala., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

The following named assistant surgeons, now at stations designated, will proceed on the mail steamer "City of Peking," to Nagasaki, Japan, and thence to Manila, P. I., for assignment to duty: F. M. WALL, C. H. STOEKLE, G. S. DEAN, F. C. GRIFFIS, W. M. ROBERTS, W. H. TEEFT, J. W. HOLLAND, T. J. STRONG, C. C. WHITCOMB, D. H. LAMB, L. A. SPAETH, OSCAR F. DAVIS, E. F. SLATER and G. M. VAN POOLE, Army General Hospital, Presidio; W. E. CHAPMAN, E. E. LAMKIN and R. B. GRUBBS, Presidio.

Changes in the Medical Corps of the U. S. Navy, for the two weeks ended August 25, 1900:

ELMER, M. K., assistant surgeon, commissioned assistant surgeon from July 18.

LOWNDES, C. H. T., surgeon, commissioned surgeon from June 7.

GARTON, W. M., assistant surgeon, is detached from the "New York," and ordered to the "Massachusetts" immediately, temporarily, by the commander-in-chief of the North Atlantic Station.

COSTIGAN, C. D., passed assistant surgeon, is ordered to the "Monocacy" for additional duty with regiment of marines.

LUNG, G. A., passed assistant surgeon, is ordered to the "Monocacy" for additional duty with regiment of marines.

KENNEDY, J. T., passed assistant surgeon, is ordered to the "Monocacy" for additional duty with regiment of marines.

DAVIS, E., assistant surgeon, is ordered to the "Yorktown."

ALFRED, A. R., passed assistant surgeon, is ordered to the "Castine."

VON WEDEKIND, L. L., passed assistant surgeon, ordered to temporary duty at the headquarters of the Marine Corps, Washington, D. C., August 22, and then to the "Richmond."

WAGGENER, J. R., medical inspector, transferred from the naval hospital, Cavite, P. I., to the naval hospital, Yokohama, Japan, for treatment.

PICKRELL, G., surgeon, detached from the naval hospital, Yokohama, Japan, and ordered to the Cavite Naval Station.

NORTON, O. D., surgeon, detached from the "Monocacy," and ordered to duty with the marine regiment in China.

DOUGLASS, S. W., pharmacist, detached from the "Massasoit" and ordered to the Key West Naval Station immediately.

Changes in the U. S. Marine-Hospital Service, for the two weeks ended August 25, 1900:

WHITE, J. H., surgeon, to proceed to Jacksonville, Fla., as inspector, August 10. To proceed to Camp Perry, Fla., as inspector, August 14.

FICKES, L. D., assistant surgeon, detailed by chief quarantine officer of the Philippine Islands as quarantine officer at Iloilo, P. I.; confirmed by department approval August 15.

THORNBURY, F. J., assistant surgeon, is granted leave of absence for 3 days.

STANSFIELD, H. A., assistant surgeon, is detailed by chief quarantine officer of the Philippine Islands as quarantine officer at Cebu, P. I.; confirmed by department approval August 15.

MCISAAC, F. C., acting assistant surgeon, is granted leave of absence for 14 days, from August 3.

HOLSENDORF, B. E., hospital steward, letter of July 20, 1900, granting Hospital Steward Holsendorf leave of absence for 30 days, amended so that said leave shall be for 15 days only.

WARHANI, C. A., hospital steward, is relieved from duty at New York, N. Y. (Stapleton), and directed to proceed to Vineyard Haven, Mass., and report to the medical officer in command for duty and assignment to quarters.

PURVIANCE, GEORGE, surgeon, will report at Washington for special temporary duty, August 20. To proceed to Baltimore Quarantine station as inspector.

CARTER, R. H., surgeon, granted leave of absence for 20 days from August 24. August 21.

WHITE, J. H., surgeon, to proceed to Baltimore Quarantine Station as inspector, August 21.

MCINTOSH, W. P., surgeon, granted leave of absence for 7 days. August 17.

THOMAS, A. R., passed assistant surgeon, granted leave of absence for 1 month from September 15.

COFER, L. E., assistant surgeon, granted leave of absence for 1 month and 10 days from September 21.

BROWN, B. J., acting assistant surgeon, granted leave of absence for 14 days from August 12.

McKAY, W. W., acting assistant surgeon, granted leave of absence for 4 days, August 21.

STATON, LEE W., acting assistant surgeon, granted leave of absence for 10 days from August 12.

LAGRANGE, J. V., hospital steward, granted leave of absence for 10 days from September 11.

MORRIS, GEORGE A., of Michigan, appointed junior hospital steward, August 15.

Foreign News and Notes.

GREAT BRITAIN.

Plague in Glasgow.—Three cases of plague are reported in Glasgow. A member of the family (father, mother and child) having died on Tuesday, 40 families living in their neighborhood have been isolated. The death was the second resulting from the plague.

Midwives and Puerperal Fever.—Recently a midwife at Westminster was charged with manslaughter. A patient whom she had attended died of fever, and she was warned by the coroner and vestry officials not to attend another confinement for 6 weeks. She did so in defiance of the warning and her next patient caught the disease and died. The prisoner was discharged, as there could be no proof that the fatal disease was actually communicated by her.

Anthrax from Eating Veal.—A laborer at Crophorne died a few days since after eating the flesh of a calf which had suffered from anthrax, and another man is very ill from the effects of a similar meal. Unfortunately, the report contains no information as to the symptoms. Infection via the stomach is an extremely rare occurrence; indeed, we cannot recall a previous instance of the kind, though possibly its occurrence might help to explain some of the mysterious deaths at present attributed vaguely to ptomain poisoning.—[*Medical Press.*]

The Study of Inebriety.—The Society for the Study of Inebriety has appointed a committee of medical men to inquire into the relation of heredity to the production of inebriety. Much progress has been made with the investigation. The committee are fully satisfied that drunken parents tend to have children who become drunkards, but they earnestly desire to obtain evidence bearing upon the question whether a parent who himself inherits no special tendency to inebriety can, as the result of mere intemperate habits, entail upon his children a potential inebriety.

A Backward Lunatic Asylum in Carnarvon.—According to the *Medical Press* the annual report of the Commissioners in Lunacy reveals a scandalous state of affairs in the North Wales Asylum at Denbigh. Among the many defects was a faulty drainage system and bad construction in the epileptic wards, so that the inmates cannot be properly

supervised. There are 40 more patients in the asylum than the number provided for. The wards are dull, gloomy, and cheerless, and few amusements are provided for the luckless inmates of this Welsh Bastile. Keys admitting to the female wards are allowed to the workmen, and there is a dangerous mingling of sexes in the laundry. The staff is reported to be entirely too small, and the high death-rate is attributed to insufficient ventilation combined with overcrowding.

An Embalming School for London.—The question of funeral reform has received some attention in England, though its discussion is apt to be shelved as too painful. It is probable that there may be differences of opinion as to whether the introduction of the practice of embalming would be a reform or not. Though rare in England, in the United States it is so widespread as to be quite general. Embalmers are, as a rule, licensed by the State Boards of Health, which often lay down stringent regulations with regard to the transportation and the treatment of the dead, more particularly where death has been the result of an infectious illness. Funeral customs in England differ so widely from those in America that it is doubtful whether embalming will find favor there. A course of lectures will be given by Professor C. Renouard, of New York, at the University College.

Grocers as Chemists.—An inquest was held on the body of a child at Lancashire recently after taking a portion of "headache powder." The evidence showed that she had been a healthy child and while playing in the street complained of headache. A "headache powder" was obtained from the local grocer, and the child was given half. She became ill during the night, and died before medical aid could be obtained. The jury returned a verdict of "misadventure through taking an overdose of acetanilid." The British Pharmacopoeia considers 3 grains of acetanilid as an adult dose, but the child had been given more than this, though only half the powder. As, however, in 1898 the Pharmacopoeia had fixed 10 grains as a maximum dose, the jury decided that the maker of the powder was not guilty of criminal neglect. For some occult reason phenacetin, antipyrin, acetanilid, and other reputed remedies for headache, are not scheduled in the list of poisons, and, owing to the danger involved in taking an overdose, there is surely scope for an extension of the Sale of Poisons' Act. Any grocer or other unlicensed person, as the law at present stands, does not infringe any statute by selling these drugs, and no objection would be raised if a layman ordered in his acetanilid or antipyrin by the ton. There is no check on the sale of these dangerous "cures." It is stated on good authority that one firm alone, that supplies grocers all over the country, advertises that the yearly sale amounts to hundreds of tons of this "headache powder."—[*Physician and Surgeon*]

Adulterated Vinegar.—In his annual report for the Parish of St. James, Westminster, Dr. Edmunds draws attention to several convictions which he secured under the Sale of Food and Drugs Act, against vendors of vinegar which was either not of the required strength or which had been treated with sulphuric acid. A pure malt vinegar should contain nothing but what is furnished to it by the barley, yeast, and water used in its manufacture. While it is true that mere traces of sulphuric acid may find their way into such a vinegar from the barley and water employed, it is safe to maintain that more than 0.03% of sulphuric acid has either been added to the vinegar or to the materials out of which it is made. Sometimes it is poured into the finished vinegar to preserve it, or is added to the grain in order to reduce it to a really fermentable substance. As to the strength of vinegar, an old Act, since repealed, fixed the strength of proof vinegar as a little over 6% by weight of real acetic acid. Such a vinegar keeps well, and acts efficiently as a preservative, whereas much weaker vinegar does not fulfil either requirement, and for dietetic purposes a vinegar can always be diluted to the consumer's choice. The Government Laboratory at Somerset House regards the acetons strength of commercial vinegar as amounting to at least 3% of real acetic acid. The result is, as pointed out by Dr. Edmunds, that makers of cheap vinegars water down their vinegar to just above 3% bottom limit.

CONTINENTAL EUROPE.

The Moscow Prize.—The prize of \$1,000, established at the Twelfth International Medical Congress at Moscow, in 1897, for medical work of the greatest benefit to humanity, has been awarded to Professor Rá non y Cajal, for his researches on the minute structure of the nervous system.

Cobwebs as a Styptic.—It is an ancient practice, in certain parts of the country, to apply spiders' webs to a bleeding point in order to control the hemorrhage, regardless of the fact that a poisoned wound or even tetanus may be the eventual sequel of this rough and ready dressing. In a recent paper read by Monsieur Pécus before the Central Veterinary Society of Paris, he described the case of a horse which was hurt in one of its forelegs. Spiders' webs were applied to stop the bleeding; soon afterwards the leg became swollen and the animal developed horse-pox. After careful investigation it was found that the cobwebs had been obtained from a cow-house where several of the cows were suffering from cow pox, and the infection had been conveyed in this way. Monsieur Henri de Parville holds the view that spiders' webs are a source of infection owing to the presence of microbes brought to the webs by the medium of flies.—[*Physician and Surgeon*.]

MISCELLANY.

Cholera in India.—The present epidemic of cholera in India is one of the worst outbreaks on record. The natives are said to be dying at the rate of 3,000 a week. The epidemic is undoubtedly due to the pollution of the scanty water-supply during the famine.

Emperor of China Said to have Cancer.—Dr. Bachman of Shanghai asserts in the *Gegenwart* that Emperor Kwang-Su suffers from cancer of the throat, and that he is unable to reign. The same view is taken by Dr. Dethier, a French physician, and by Dr. Sheng-Liang-Feng, both of whom have examined the Emperor.

Elephantiasis.—It has been announced that the second malarial expedition of the Liverpool School of Medicine has discovered the distributing agent of elephantiasis. The parasite was found in the proboscis of the mosquito, which of course suggests the probability of that insect being the actual means of conveying the filaria to man. A similar discovery has been made in England by Dr. Low, in the case of mosquitos sent from Australia, and from Captain James in India.

The Cost of Disinfection.—The taxpayers of Sydney, Australia, will have reason to regret not having kept the city in better order, since the cost of disinfection and cleansing necessitated by the recent outbreak of plague is about £100,000. The amount can cause no surprise when one learns that some 5,000 dwellings had to be cleaned, along with 808 shops and houses, 303 yards and stables, 314 warehouses, and 107 factories and mills, and these figures do not include wharves or places where the cleansing process is still going on.

Obituary.—JOHN ANDERSON, of New Cross Road, S E, August 9, aged 82.—KINGSFORD BURR, at Salisbury Road, Hove, August 10, aged 79.—FREDERIC BLAKESLEY MALLET, Newport House, Bolton, August 8, aged 59.—WILLIAM DREW PARSONS, of Liverpool, August 7, aged 84.—DANIEL JAMES O'CALLAGHAN, of London, aged 85.—NICHOLAS CRETZULESCO, of Bucharest, aged 92.—ANDREW HENRY BLAKE, of Bayswater, August 10, aged 60.—SAMUEL WAGSTAFF SMITH, of Cheltenham, August 12, aged 65.—JAMES HENDERSON STEPHENSON, of Glasgow, August 2, aged 47.—JAMES HENRY RICE, of Sandbach, August 8.

Medical Schools in China.—There are only 2 medical schools in China, 1 at Hongkong and 1 at Tientsin, and these are of recent date. The great mass of Chinese practitioners have learned their physic out of books of magic. A plaster (a soft one) is applied to a broken leg; a live duck split in two is the common poultice. Duck's blood is smeared on the face to relieve fever and headache, and "dragon's" blood and deer's horn are the popular remedies for leprosy. The most important part of the treatment for all diseases, however, is the burning of printed emblems, beseeching the evil ole to ward off illness and death.

The Latest Literature.

1. The Maternal Mortality in Childbed. WILLIAM J. SMYLY.
2. On the Prevention of Insanity. R. PERCY SMITH.
3. Ocular Headaches. W. A. BRAILEY.
4. Introductory Address—Nasal Obstruction. SCANES SPICER.

1.—Smyly states that in the first half of the present century the mortality among parturient women, especially in hospitals, was probably greater than in any other period of the world's history. Towards the close of the 70's, however, a sudden and satisfactory change took place, and the mortality has dropped from 9% to less than 1%; the greatest improvement being in that class of cases in which death was due to puerperal fever. This was owing to the recognition that infection could be carried from one patient to another by the physician or other attendant, and to the introduction of antiseptics into obstetric practice since 1870. Next to the introduction of antiseptics, he considers the substitution of external for vaginal examination of parturient women as the most important advance in modern midwifery. He endorses the opinion of Créde, who wrote as follows: "Even the simplest manipulation may cause infection. It should therefore be laid down and taught as a fundamental principle that internal examination of parturient women should be altogether avoided or restricted within the narrowest possible limits; it can be very well replaced by external examination. To instruct their pupils as thoroughly as possible in this method is the present and future duty of teaching institutions." Smyly believes that external examination is not only safer but that it gives more information to the examiner, is easier and more reliable. Not only has his own experience proved this, but in the Rotunda Hospital, where the students are obliged to write down upon the bedcards the result of each examination, mistakes in diagnosis were much more frequent with the vaginal than with the external or abdominal method. If, however, vaginal examination is necessary, as it is under certain conditions, then aseptic rules should be most carefully observed. It is thought that in the maternity mortality in private practice there has been far less improvement than in hospitals, and he urges the faithful observance of the principles herein sketched by all who have the care of parturient women. [W.K.]

2.—There was an increase of 3,114 in the number of insane in England and Wales under the care of the Commissioners in Lunacy, in 1898. This increase has affected all classes; the private class, the pauper class, and the criminal class. There was an increase in the rates of the insane so that there was 1 insane person to every 302 individuals. Inheritance is the largest cause of insanity. As shown by statistical tables the presence of insanity in a family demands from its members at least some serious reflection before marriage is entered upon. In this connection it is often in the power of medical men to give advice that may prevent the union of two bad stocks. The existence of insanity is concealed where large property is concerned and where there are several marriageable daughters in a family of limited means and where it is thought that the avowal of insanity in the family will "ruin their chances," as if the chief object in life were to propagate defective individuals. Again, concealment may take place from ignorance or carelessness. In the case of persons who have themselves suffered from a definite attack of insanity marriage should be absolutely forbidden. The popular idea is that the patient is sure to be all right when she is married, and medical men have not always the strength of mind to inform the relatives that the likelihood of insanity after childbirth is greater in such cases than the likelihood of stability. A congenital imbecile should not be allowed to marry and marriage should not be permitted in the case of chronic epileptics. Next to heredity, alcohol figures most largely in the causes of insanity. Statistics show the effect of alcohol on the individual alone and take no note of alcoholic inheritance as leading to the production of insanity, idiocy, alcoholism, hysteria, epilepsy, or

other neuroses in the offspring. Acquired syphilis is one of the most potent predisposing causes of general paralysis, and recently cases of juvenile general paralysis have been recorded, in practically all of which a history of parental syphilis was found. Smith believes that for the prevention of insanity the profession, at least, should seriously consider methods of reducing the propagation of the race by those of insane inheritance or those who have suffered from insanity. That it should consider the influence of alcohol in the production of insanity and the need for preventive legislation. And that it should consider the causation of general paralysis by syphilis and the advisability of registering syphilis so that it may be controlled. [J.M.S.]

3.—Bailey discusses ocular headaches, that is headaches in association with refractive and muscular errors. Muscular errors are by far the most important; other influences are glare and sudden irregularities in the distribution of light. Both the intrinsic and extrinsic muscles of the eye are concerned. Defects in accommodative movements are responsible for most of the ocular headaches. It is a general law that the larger the ocular error the less the tendency to headache; but both spasm and headache are produced more by moderate inequality of refraction, especially if it be astigmatic, and most of all by astigmatism with asymmetry of the axes. Errors of the extrinsic muscles produce headache, but less than the accommodative muscles, though more migraine, more giddiness, and more general distress. Another factor in headache is the tendency to binocular vision, and so the rule: the stronger the tendency to binocular vision the more headache produced by an error of the recti and oblique muscles. [A.B.C.]

4.—In his address before the Section of Ophthalmology and Laryngology, Spicer said there could be little doubt that in the past the specialist was only too often a mere skilled artisan, working in a groove, and with no eye for any considerations outside, and with little conception of the relations and interdependence between the phenomena of his field and those of the organism generally and the external world. Thus he deserved many of the reproaches that were levelled at him. At the present day, however, all that is changed, and any specialist worthy of the name, is not only a master of his special technic, but has a real living appreciation of physical, chemical, and biologic sciences, a thorough knowledge of the principles and up-to-date practice of medicine and surgery, and he also takes a wide, philosophic outlook from the evolutionary and developmental standpoint, and is ready to apply light from each of these sources to the elucidation of each problem that confronts him. He further said: To this newest generation we have good reason for self congratulation that we belong. For whereas we find in our own country that the men who are now holding aloft the standard and fighting in the front rank as specialists in our branches, are men who have won their spurs by gaining the highest university and academical distinctions in original, scientific researches, and in honorably maintaining the efficiency and reputation of our art in practice; on the other hand, on the Continent, and in America, we find the universities giving to our specialities and their professors a recognition equal to that of any other branch of medicine or surgery, even selecting from among our ranks to the post of University Professor of General Medicine one who has devoted his life to our speciality. I refer to Professor von Schrötter, of Vienna. It cannot be long now before laryngology and otology take full rank in all university and qualifying tests in this and all countries. The author discussed nasal obstruction, saying that such obstruction to the passage of the inspiratory current will necessarily be followed by a fall of air-tension behind the obstruction. This leads to changes in the membrane, lining the various air-passages, and sinuses, and consequent pathologic changes. He believes even the very slight obstructions which tend to persist are capable of setting up this abnormal condition. Most cases of nasal obstruction are due to injury, and this may follow, even though the injury be very slight. Frequently, patients are submitted to an operation for adenoid growths, whereas the trouble is due entirely to nasal obstruction. Very often, postnasal adenoid hyperplasia does not exist, or is very insignificant. He says that hundreds of operations for adenoids are done unnecessarily every year. Great stress is laid upon the prevention of nasal obstructions by prophylactic treatment in early life. [A.B.C.]

9. A Case of Foreign Body (Clinical Thermometer) in the Bladder; Lithotripsy; Recovery. JOHN H. MORGAN.

3.—From examination of lesions resulting in the treatment of urethral strictures Harrison concludes that in **periuethral strictures** of the deep urethra division as practised in Perreve's and Holt's operation may be limited to rupturing the dense stricture bands in the submucosa, whilst the mucous membrane itself escapes any injury. In such cases permanent cure may result. On the other hand, where the mucous membrane is in itself the seat of stricture it is necessarily torn or lacerated by sudden division, exactly as from traumatism of accidental external violence which are followed by strictures of the most contractile and recurrent form. When the entire thickness of the stricture can be included within the incision of moderate dimensions made by an internal urethrotome the normal caliber of the urethra may be completely and permanently restored. When this happens all the fibers of contraction constituting the stricture are divided at the operation. Absence of recurrence under such circumstances is not necessarily dependent on the use of the bougie, though it should be invariably advised as a precautionary measure. Multiple strictures or strictures of the deep urethra treated by internal incision have a tendency to recur. In case of recurring strictures previously treated by incision and in primary strictures of much length there is doubt whether it would be safely possible to perform the internal operation. Such wounds should be made with due regard to other surgical principles in addition to the one pertaining to the division of the contraction. The tendency to recurrence of stricture after internal urethrotomy is largely diminished by the employment of systematic and efficient urine and wound drainage, such as the combination of external urethrotomy or perineal puncture affords. [M.B.T.]

4.—Semon mentions the following indications for the performance of **thyrotomy**. The operation is advisable for the removal of such foreign bodies as it has been found impossible to remove by ordinary means through the natural passages. It is considered a procedure of slight risk. It is also indicated in rare cases of injury to the larynx in order to replace dislocated fragments in case of severe fracture of the larynx, and, if necessary, to retain them in position by a tube introduced through the mouth or from a tracheotomy opening. Laryngocele or laryngeal air-cysts are also extremely rare. If symptoms are threatening thyrotomy with extirpation of the cyst is indicated. In case of stenosis of the larynx which may result from ulceration of the mucous membrane from perichondritis, particularly of syphilitic origin, hyperplastic inflammatory processes, congenital webs, adhesions between the vocal cords, ventricular bands or ulceration from external wounds, scalding, syphilis, typhoid fever and other causes, or in narrowing following the use of O'Dwyer's tubes, thyrotomy may be indicated. The indications for thyrotomy in acute laryngeal perichondritis are extremely rare. In case of **laryngeal tuberculosis** Goris has recommended the operation if the lesions be circumscribed and if the general nutrition of the patient is good, even though the lungs be much affected. It is not desirable in case the general health is very bad. Goris and Semon have both had successful results following thyrotomy with removal of the ulcerating surface, scraping the base of the ulcer and the application of pure lactic acid. Semon's case remains cured 3 years after operation. A danger in these cases is from tuber-

culous infection of the wound. The operation has been once successfully performed for lupus of the larynx. Scleroma of the larynx is a rare indication for the operation. It may be required in case of benign growths in which it has been found impossible to remove the growth by the intralaryngeal operation. The operation is most frequently indicated for the removal of malignant growths, and in order to be successful it must be undertaken very early. The growth itself with a zone of surrounding healthy tissue should be removed and the operation should be performed only in cases in which the disease is limited and situated within the larynx without infiltration of the cervical lymphatic glands. Semon has succeeded in curing 83.3% of all patients upon whom he has operated. [M.B.T.]

5.—In the case of a woman who cut her thumb, there was considerable hemorrhage from the wound, and healing was delayed. About 3 weeks after the accident, the patient had an attack that was characterized by swelling of the left side of the face, with redness, heat, and pain. The swelling was edematous in character and involved the region of the parotid gland, the cheek, the nose, the lips, and the eyelids of the left side. The involved area was covered by a small, vesicular eruption. On examining the urine of this patient, Surveyor added a drop of strong caustic soda solution to the sediment obtained with the centrifuge and noted the development of a bright, pinkish-purple color. The patient had been taking a mixture containing carmine as a coloring-matter, and the author thought that some idiosyncrasy on the part of the patient caused abnormal excretion of the substance; but, in a second attack of the trouble, carmine was withheld and the reaction occurred just the same. The administration of carmine to other individuals failed to produce the reaction. The author is of the opinion that the reaction is a specific one characteristic of a new disease. [J.M.S.]

6.—Freeman defines **eczema** as a serous inflammation of the skin not produced by any form of external irritant. He believes that the disease is caused by a specific organism, possibly the "monococcus" of Unna. Among other dermatologic conditions that may be confounded with or that are closely allied to eczema are pyoderma, psoriasis, seborrheic dermatitis, dermatitis herpetiformis, granuloma fungoides in its early stages, lupus, seborrhea, and impetigo contagiosa. In the treatment of the condition the author lays much stress on cleanliness and the removal of crusts regularly. He thinks very highly of dusting powders of French chalk, oxid of zinc, or starch. Less value is attached to the general than to the local treatment of the affection. [J.M.S.]

7.—Wood reports a case of **puerperal septicemia complicated with phlegmasia** treated with antistreptococcic serum, in which he considers the favorable result largely due to the use of the serum. There were in this case no bad or uncomfortable after-effects of any kind from its use. [W.K.]

8.—Fenwick suggests that the **cardiac irritability** noted in cases of **convalescent typhoid fever** are due to a sympathetic disturbance arising in the superior mesenteric plexus and thence transmitted to the cardiac ganglia and plexus. The superior mesenteric plexus supplies that portion of the intestine chiefly attacked by the typhoid poison and is very closely connected to the cardiac plexus. [J.M.S.]

9.—A woman of 32 entered the hospital with very severe symptoms of cystitis and stone in the bladder. Lithotripsy was performed and in washing out the crushings several particles of glass and globules of mercury were found to be mixed with the fragments of the stone. The remnants were boiled with strong HCl and filtered and the glass and mercury remained. An examination of the fragments showed that the glass and mercury were probably from a **clinical thermometer**. It was impossible to determine from questioning the patient when or how the thermometer was introduced into the bladder. [M.B.T.]

2.—Beck describes a new and ingenious method of operating on **exstrophy of the bladder**. The margins of the exstrophied bladder were freed and dissected up for about 1 cm., which allowed the freshened edges to be easily approximated. Both recti muscles were then exposed and incised along their internal margins to the extent of a little less than half their thickness. Two transverse incisions, one just above the symphysis and the other just below the umbilicus, connecting the outer and inner margins of each rectus muscle and extending down into the substance of the muscle for half its thickness, completed the outlines of the flaps. Beginning at the internal margin of the incision, the upper layers of fibers of the recti muscles were divided, until the flaps so formed could be lifted near their outer margin, with which they remained connected after the manner of a hinge. The bladder walls now being united with thin iodoform-silk sutures the reflected muscular flaps were united above them. [G.B.W.]

3.—Bullard reports the case of a cyst on the anterior surface of the **epiglottis**. It was about the size of a small filbert and had a broad base. It was finally cured by incising and cauterizing the inside of the sack with a chromic acid. [G.B.W.]

4.—The case reported by Stinson was one of **phosphatic incrustations on the bladder-wall** with the formation of numerous small calculi, which persisted seemingly in spite of all treatment. Finally a median lithotomy was done and the crustations carefully and thoroughly removed, though this was not accomplished without considerable difficulty. A drainage tube was left in the perineal wound for 6 weeks, the wound healing within 3 days after its removal. During the treatment following the operation it was found that the only solution which would keep the urine acid and prevent the formation of incrustations was a **solution of quinin**, 2 grains to the ounce of a 1 to 10,000 solution (at first) of sulphuric acid. A good recovery was finally secured, and at the time of the last report the patient's urine and micturition were normal. [G.B.W.]

5.—This patient had been gored by a cow and when found had two loops of his intestine protruding through the wound. One of these loops had been badly torn, necessitating resection and **anastomosis with a Murphy's button**. After carefully washing the intestines and abdominal cavity with hot normal salt-solution the abdomen was closed with silk-wormgut sutures. The patient was discharged from the hospital cured on the thirty fifth day. [G.B.W.]

6.—Glasgow says that it is now generally admitted that **asthma is a vasomotor neurosis** and that the paroxysm is provoked by some peripheral irritation of the sympathetic nerve. This irritation usually lies on either the posterior surface of the turbinates, the interarytenoidal commissure, the posterior surface of the trachea or the membrane at the bifurcation of the trachea, as these have been demonstrated to be the most sensitive areas in the respiratory tract. It is unquestionably an irritation of one or more of these areas which produces reflex cough and it is most probable that a similar irritation produces the symptoms of asthma. According to Glasgow's experience the interarytenoidal area seems to be the most frequent site of the irritation and this in many cases is due to a primary laryngitis, entirely independent of any pathological condition of the nose. He reports a number of cases in support of this latter assertion, all of which were apparently cured by the laryngeal applications. He ends his article by saying that constitutional treatment is a necessary adjunct to the local because in almost all cases there is an inherited tendency toward the disease which can only be successfully combated by keeping the patient in the best of health. [G.B.W.]

7.—Hopkins has found, after a rather extensive use of **suprarenal extract** in intranasal operations, that there is a marked tendency towards secondary hemorrhage, the bleeding coming on in from 2 to 4 hours after the operation. He has written to a number of specialists, and with one exception they all report finding the same trouble. He believes that the mixture of cocain and suprarenal is followed by relaxation sooner than when the suprarenal is used by itself in the majority of cases. After operating in the nose when suprarenal is used it is best in every instance to pack the fossa and so be on the guard against the secondary bleeding. A by far less common sequel to the use of suprarenal is an intense coryza, induced by the secondary relaxation. Hopkins reports 2 such cases. [G.B.W.]

1.—In order to avoid possible errors by false interpretation of x-rays Beck calls attention to the following sources of error. Without a thorough knowledge of anatomy normal structures may be mistaken for foreign bodies or severed fragments from fractured bones. The carpus is especially likely to produce such errors. The os trigonum tarsi has been mistaken for a fragment severed from the astragalus. Muscular sesamoids may also mislead. Unless the time of ossification of various epiphyses is remembered they may be mistaken for lines of fracture. The normal skeleton should always be compared with the skiagraph and it should be particularly remembered that certain pathologic conditions, such as rachitis, influence the outlines of bones and may be supposed to represent a portion of an injury. The intraarticular fractures offer the greatest diagnostic difficulties, as the fracture-line is also often obscured by callus formation. If a skiagraph of the other joint is made at the same time, in the same position, and in the same projection, the shadows will be correctly understood and interpreted. In oblique fractures with no lateral displacement it may be necessary to take at least 2 skiagraphs in different planes before the injury will be recognized. Misinterpretations have also arisen from **mechanical and chemical defects**, causing markings in the photographic plate. [M.B.T.]

2.—Jones says that experiments have proved that it is possible for the **dust laden with bacilli from dried sputum** to infect guineapigs by inhalation, and also fine droplets of mucus expelled by tuberculous patients by forcible exhalations as coughing or sneezing will do the same. In the latter, close proximity and frequent attendance are necessary when this is applied to attendants on such patients. Strauss made cultures from the contents of the respiratory portions of the nasal cavities of 29 hospital patients and employees who were not tubercular, and these cultures were injected into the peritoneal cavities of 29 guineapigs. Seven died of acute peritonitis or septicemia, and 9 of tuberculosis, showing the bacilli to have been present in the noses of 40.9% of the individuals. The author made cultures from the respiratory portions of the nasal cavities of 31 healthy persons not connected with the haunts of tuberculous patients or with laboratories. The cultures were injected intraperitoneally into 31 guineapigs. One died in a few hours of septicemia, 1 in 3 days of peritonitis, 22 of pulmonic lesions of unknown origin and in which negative bacteriologic results were obtained, 3 of pyemia, 1 was drowned, and 3 died positively of tuberculosis. The results show that *Bacillus tuberculosis* was present in 10.3% of these healthy individuals. One of the 3 was a second-hand furniture dealer, and the other 2 were students. [J.S.]

3.—Gordon reports the case of Mrs. S—, aged 45,

mother of 8 children. She had typhoid at 35, since when she has not been strong. She presents some features of being a degenerate. Menstruation was always normal. Following several severe family illnesses, she developed sudden **anuria**, but no signs of the effects of suppression of urine could be seen. There was no vomiting, no discomfort except the mental effect, the bowels were regular, and there was slight perspiration at one time with no urinous odor. The treatment was milk and other fluids freely, strychnia, and hot applications to the back. The only signs of hysteria were anesthesia of the sole of the right foot and narrowing of the visual fields. About the fourth day the patient was told that frequent applications of a lotion of chloroform and alcohol over the kidneys would positively cure her, and on that day she passed over a pint of urine. She was entirely well the next day. Four days later she developed sudden retention, and this continued until she was assured that similar applications of a lotion of alcohol and tincture of opium over the bladder would remove her trouble, and after the first rubbing she was cured. Three weeks later her visual field was found to be much larger and the plantar anesthesia was replaced by a pharyngeal anesthesia. The author explains this anuria and retention as follows: He believes in the theory of ameboid movements in the neurons. In the formation of a habit, the ends of the neurons are brought frequently in relation, and automatic action takes place when the relation of contact is established. In this case, a psychical influence—mental strain—broke up the normal equilibrium of the neurons in the brain and cord so that normal contact was interrupted, and a reflex reaction was produced in the renal center. Suggestion,—a new psychic phenomenon,—re-established the lost equilibrium. The intense moral impression of mental strain acting on the cerebral centers produced a reflex action affecting the vasomotor centers in the medulla and cord. These centers send fibers through the sympathetics to the renal plexus, from which muscular fibers go to the bloodvessels of the kidneys and contract them, causing suppression. Similar reflexes in this case affected the center in the cord for contraction of the vesical sphincter. [J.S.]

4.—Otis thinks that, in describing the advantages of a **health resort**, an accurate, full, and reliable classification is necessary, and he advises placing them under 2 main heads: 1. Natural advantages, including climatic data, as temperature, moisture, etc., elevation from the sea, configuration of land, existence and form of water-courses, character of soil and vegetation, and presence of insect-life. 2. Artificial advantages, including population, drainage and water-supply, existence of a reliable health-board, characteristics of the town (buildings, churches, streets, amusements), roads, hotel accommodations and expense of living, food-supply, sanitation, medical science, etc. [J.S.]

5.—Peckham discusses the pathology, symptoms and treatment of **tuberculous arthritis of the knee** briefly. He disagrees with Nichols in his statement that the disease usually begins in the epiphysis and believes that there are many cases in which the synovial membrane is first affected. He advocates conservative treatment, fixation with plaster of paris and taking the weight off the diseased limb in many cases. If these measures fail arthrectomy is generally required—excision occasionally and amputation as a saving measure. He reports 5 cases in which he has successfully performed arthrectomy. [M.B.T.]

Medical News.

August 25, 1900. [Vol. lxxvii, No. 8]

1. The Construction and Management of Small Cottage Sanatoriums for Consumptives. ARNOLD C. KLEBS.

3. Tuberculosis and Modern Methods for its Prevention. H. H. VINKE.
4. The Abortive Treatment of Acute Mastoiditis. JAMES F. MCKERNON.
5. Medullary Narcosis During Labor. A Preliminary Report. S. MARX.

1.—Klebs favors the erection of **sanatoriums** for the treatment of **tuberculosis**, in various parts of the country, and not far from the large cities, which offer the

chief source of supply of patients. In them the patients should be taught the hygienic measures necessary to prevent the spread of the disease, and they in turn will become teachers to other sufferers not able to be in the institutions. The chief aims in view in the erection and management are: To supply the greatest possible amount of fresh air and sunlight; a supply of good food, easily obtained if near a large city; protection from reinfection; cheerful surroundings, with means of occupation, recreation, and entertainment for the inmates during their long confinement; a strict, daily regime adapted to each individual case; instruction in hygienic measures; a corps of physicians, nurses, and assistants to carry out therapeutic measures. Sanatoriums should be small, so that the number of patients may be limited, in order that the medical adviser may be able to have the proper supervision over each case. The author's plan is a building consisting of 3 cottages joined by 2 galleries. The main or central building contains on the first floor the offices and bedrooms of the superintendent or head nurse, and on the second floor rooms for bed-ridden patients, with balconies on the southern exposure, where the beds can be wheeled during the day. The laundry and other necessary adjuncts are in wings or annexes to the north. The galleries connecting the other cottages with this one are open on the south, and can be opened on the north as well in summer. The roof is arranged to admit sunlight to all parts, but it may be excluded when necessary. This arrangement admits fresh air and sunlight both in winter and summer. The other 2 cottages contain separate rooms for each patient, facing the south, and with the corridors on the north, with windows reaching to the floor and opening out on verandahs. Bath-rooms and water-closets are in easily accessible annexes, and each room has a separate water supply and a portable bath-tub that may be placed under the bed. [J.S.]

2.—Grady speaks of the great importance of **care of the mouth and teeth in children** as a prevention of caries and also diseases of the digestive tract and systemic disorders. For 20 years he has been a visiting dentist to schools and also has a large practice among children. He strongly advises as prophylactic measures the routine examination of teeth in schools, and instruction of the pupils in the use of the tooth-brush—an unknown article to most of them. Dental inspectors are appointed by the school boards in Ontario. He suggests that members of the graduating classes in dental colleges be appointed as voluntary inspectors. This examination of the teeth is as important as teaching physiology or physical culture or music, and he thinks the best way to educate the public is through the school children. A tooth-brush drill should be part of the instruction, showing them how to brush the upper teeth downward and the lower ones upward, and then following this by rinsing the mouth with water or some mild antiseptic solution, with the lips closed, and forcing the water through the crevices between the teeth. [J.S.]

3.—Vinke states that all the other contagious diseases combined do not cause so many deaths as **tuberculosis**. Neither the bacillus nor hereditary tendency alone can cause the disease, but both must be combined. We cannot change faulty inheritance, but we can limit the possibility of infection, and as the most frequent source of this is from inhalation of dried sputum in dust, it is essential to teach the laity the dangers of such infection and to disinfect all sputum from tuberculous patients. Those having the disease should be isolated in suitable sanatoriums, when possible. All meat and milk, particularly when ingested by children, should be rendered noninfectious. He lays much stress on the early recognition of phthisis, so that these measures may be carried out as soon as a patient is dangerous to others. In addition to the usual signs in the incipency, he mentions a slight afternoon rise in temperature not otherwise accounted for; a fairly constant dilation of the pupils; and an increased frequency in respiration. [J.S.]

4.—M. Kernon enters a strong protest against the use of moist heat in cases of **mastoiditis**, while, on the other hand, he believes thoroughly in the application of cold over the inflamed area. His method of treatment is, first, to establish free drainage through the external canal, widely incising the drum-membrane, if the opening made by nature is not already sufficient; a purgative is given, and an ice-coil is applied snugly over the mastoid, and left in place for 24 hours.

If at the end of this time the symptoms have not markedly subsided, the coil should be reapplied for 12 hours, and a second 12 hours if necessary. If at the end of this time symptoms have not moderated or have increased in severity, operation is called for without further delay. In young children the limit of time which the coil should be applied is 36 hours; if then the pain still persists, a rest of a few hours should be granted before proceeding to open the mastoid. [O.B.W.]

5.—Stimulated by the results obtained by Tuffier and Kreis, Marx began a series of experiments in **medullary narcosis during labor**, and now gives a detailed account of 5 cases as a preliminary report. These cases though few in number warrant him in stating that in lumbar cocainization we have a method which is of the greatest value in producing analgesia, which checks almost entirely the pains of labor without, so far as his personal experience goes, the least danger to mother or child. Complications of a severe grade have never occurred from its use; but some disagreeable though evanescent features frequently occur, such as nausea, vomiting, headache, slight increase in pulse-rate and rise in temperature; these, however, seldom continue more than 8 to 12 hours. The technic in medullary narcosis is as follows: The patient's back, from the coccyx to the middle of the dorsal vertebrae, is thoroughly scrubbed with tincture of green soap and alcohol and ether. This is followed by a saturated solution of permanganate of potash which is removed by a supersaturated oxalic-acid solution. The entire area is then covered with sterile towels. A needle about 10 cm. long is employed with a metal hypodermic syringe, both of which are boiled 10 minutes. The patient is placed on the side with arched back. The thumb of the left hand is placed on the spinous process of the fourth lumbar vertebra. (This point may readily be found by locating the deep depression between the spine of the last or fifth lumbar and first sacral, the posterior landmark of the external conjugate, or, in very fat women, a line drawn joining the highest points of the crista ilii will pass over the center of the fourth lumbar vertebra and is a reliable guide.) The needle is inserted half an inch in front of and just outside the edge of the thumb at an angle of about 165°. The direction of the needle is from below upward and without inward. If the point strikes the lamina it is to be moved gently up or down until the space between the vertebra is felt. The puncture may be made either between the third and fourth or fifth vertebrae. The point is then pushed slowly and gently downward until the spinal fluid is seen running out. Ten minims of a cocain solution, representing $\frac{1}{2}$ grain, is now injected and the needle withdrawn. This is all that is necessary. In from 7 to 12 minutes after the injections the pains are very much diminished or entirely allayed, there being a sensory paralysis of the lower part of the body reaching to the umbilicus. Motor disturbances, so far as the uterus and its contractions are concerned, were not noted. The analgesia continued about 3 hours when the woman began gradually to feel the painful uterine contractions. The results in the cases reported were very satisfactory. Marx suggests the use of this method in cases of prolonged and tedious labor, as anesthesia can be produced without interrupting the course of labor in any way. He, however, is not prepared to recommend such measures in private practice until further hospital experience shall fully justify it. [W.K.]

5. Immediate Repair of Perineal Tears. E. S. BOLAND.

1.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, p. 328.

2.—Storer and Thurber report 2 cases of **ectopic gestation** and think that after one ectopic gestation a second is quite likely to occur, and both patient and physician should be on guard that the condition may be early recognized and

thus treated at the time of least danger. If diagnosis is made before rupture, the vaginal route is to be preferred, otherwise the abdominal route should be chosen unless in case of a very large pelvis. [W.K.]

3.—Davenport discusses the comparative dangers of the removal of **fibroid tumors** by hysterectomy, or of their continued existence and growth, and concludes that whenever a tumor causes hemorrhage, great pain and discomfort, or is the cause of serious embarrassment, operation may be prescribed as the best method of procedure. [W.K.]

4.—Cushing refers to the great **reduction in mortality from operations for myoma**, etc., in the last few years, and believes that total hysterectomy should be performed when the cervix is enlarged and diseased; when the cervical canal is suppurating or septic; when there is a suspicion of malignant disease; and when vaginal drainage appears desirable. Otherwise it is better to leave the whole or a part of the cervix, because there is less danger of hemorrhage during operation, or of oozing afterward; less chance of infection of the wound; and because the lower parts of the broad ligaments with the cervix form a better support to the pelvic contents than does the simple union of the vault of the vagina. [W.K.]

5.—Bland discusses the etiology, prevention, and treatment of **perineal lacerations**, and believes that if carefully carried out, the immediate operation of suturing ought to give 90% of successes, and that in many cases it can be readily done without an anesthetic, thus avoiding the need of an additional assistant and the consequent delay. The obstetrician should always go prepared to do the immediate operation of repairing perineal lacerations. [W.K.]

7. Some Observations on Intubation of the Larynx by the O'Dwyer Method, Based on 75 Cases. J. W. WEST.

1.—Byford advocates the systematic method of **inducing peristaltic action** as soon as possible after a **peritoneal section**. He first used this method for the purpose of preventing intestinal paralysis and adhesions, and he noticed in the cases thus treated a marked improvement in all after-symptoms. There were practically no temperature cases, no crying for morphia, no bloating, no fixed pains, and seldom any subsequent pain in the ovarian regions even when firmly adherent appendages had been removed. The method advocated consists of 4 drams of fluid extract of cascara, or some equivalent, 2 hours before the time set for the operation, dram doses of magnesium sulfate every hour from the time the patient awakes after the operation, and a high glycerin and water enema (2 to 4 ounces) every 2 hours, beginning 8 hours after. A high glycerin enema was given before the patient left the table after operations in which adhesions were separated and raw surfaces left. The treatment must not, as a rule, be discontinued until the patient passes flatus, not only with the enemata but freely between enemata. Means must be taken to maintain frequent peristalsis, and a daily evacuation of the bowels after the first days. To that end 2 drams of magnesium sulfate or 2 or 3 ounces of Hunyadi water are given night and morning for 2 weeks, the dose being regulated according to the effect. [w.k.]

2.—Stone summarizes the necessary treatment of cases of **pus in the pelvis** as follows: 1. The abdominal route may be selected in the vast majority of real pus cases because it not only gives a better opportunity to deal with diseased pelvic structures, but also facilitates the inspection of the abdominal viscera and the relief of any pathologic condition of these organs. 2. The vaginal route is still used by the writer as occasion demands, as when a pelvic abscess is pointing in the vaginal vault. 3. In the majority of cases, then, we would advise abdominal section. Still, in a certain small number, we advise vaginal puncture, and in a third class, when the abscess is large and situated high in the pelvis, we reach it through the abdomen, evacuate and drain without attempting enucleation if the patient is evidently too much exhausted to bear the radical operation. In short, we take the position which we think unassailable, that pus should be sought for and evacuated from that quarter which gives the easiest approach and speediest and safest exit consistent with the present condition of the patient, and having in view her permanent restoration to health. [w.k.]

3.—Sears divides **puerperal infection** into the 2 best-known forms of septicemia and sapremia, and believes that in septicemia or true septic infection the curet is contraindicated. One of the conditions favoring the entrance of the poison, is a raw or bruised surface, and as the mucous membrane of the uterine cavity forms a strong barrier to the rapid absorption of the poison, and it is impossible to remove the retained matter with the curet without removing this protective lining, and unless every particle of the septic material is removed, a sharp reaction, due to the rapid absorption of the retained contents, is noticed, and the system may be speedily overpowered by profound intoxication. Frequent irrigations with a safe antiseptic solution should be our main local treatment in these cases. The giving of the intrauterine douche should not be entrusted to the nurse, nor should it be given with a soft rubber catheter. The ordinary curved perforated, glass irrigator is the best for the purpose. In septic infection, great reliance must be placed upon alcohol, strychnin, and moderate doses of quinin regularly. The pulse and facial expression are a safer guide than the temperature. In cases of sapremia, in which there are portions of the secundes or blood-clots remaining in the uterine cavity, and in which an apparently normal convalescence of from 3 to 8 days is followed by a sharp rise in temperature, usually preceded by a chill, it is the purpose of the physician to arrest the absorption of the poison by the safest and quickest method possible. The finger, or fingers, of the physician passed into the uterine cavity to remove portions too large to be washed away, or to serve as a guide to their removal by a pair of small placental forceps, and this followed by a thorough intrauterine irrigation with sterilized water or any other aseptic, nonirritating solution, will most effectually do this. Sears also describes some cases of sepsis which have occurred in his practice which he believes to be due to infection of small tears or abrasions by thick, turbid urine. He regards these cases as cellulitis, due to the absorption of septic matter. He believes large quantities of fluid should

be drunk to carry off the large amount of waste-products eliminated from the kidney at this time. [w.k.]

4.—Lewis presents a large collection of cases of monstrosities due to **cranio-rhachischisis**, or defective closure of the dorsal commissure of the body. In considering the causes attention must first be turned to hydrocephalus, the most common of fetal diseases. The pressure of the fluid within the cavity of the developing cerebral vesicles causes an atrophy of the cerebral tissue and a stretching of the calvarial bones. The cause of hydrocephalus is considered to be a circulatory disturbance of the vascular system of the embryo, perhaps inflammatory, which causes the pouring out of the serum into the cavities of the brain vesicles. If this effusion of fluid and consequent pressure becomes active before the cranial covering can resist, amencephalus or pseudencephalus results. Many of the different forms may depend upon the time of the exertion of the pressure, thus determining whether the malformation shall involve much or little of the cranio vertebral bony covering and much or little of the brain and cord tissue. This explanation will not, however, suffice for all forms. Those malformations accompanied by retroflexion of the fetal body must have some other causation. Here enters the factor of amniotic adhesions. Bands of amnion or other foreign bodies lying within the normal facial clefts and preventing closure for a certain period may cause a wide diversity of anomalies such as harelip and cleft-palate. Pressure from adherent amnion or by bands may cause defects in limbs, so-called uterine amputations. The great vitality of embryonic tissues explains why we do not often find at birth evidences of these amniotic bands and adhesions, the lesions in question being very apt to heal with the resulting deformity. [w.k.]

5.—Res reports a very curious case of **spontaneous amputation of both fallopian tubes** occurring in a woman of 32, married for 14 years, and with one child 11 years old. She had since the birth of this child 2 miscarriages, one 12 and one 8 years ago. The physician found her suffering from severe abdominal pain, temperature as high as 103°, loss of appetite, nausea, and inability to move. A diagnosis of inflammation of the right appendage was made and operation for the relief of that condition was performed. The vaginal method was employed and it was found immediately upon bringing the uterus down into the vagina that the tubes formed only very small stumps on either uterine horn. On the right side the rest of the tube presented itself as a bluish-black sac the size of a goose egg. The uterus and the stump of the tube with the ovaries were removed and the patient made a rapid recovery and enjoyed excellent health afterward. [w.k.]

6.—Clark, in considering the conservative treatment of inflammatory conditions of the pelvic organs, reviews 17 cases reported by Stratz, and reaches the conclusion that Stratz is entirely too optimistic as to the results of the treatment by hot vaginal irrigation and hot compresses; yet recent literature upon this subject certainly demonstrates that these remedies, which of late years have not been so freely used, should again be employed more generally. **Acute pelvic inflammatory cases** without the formation of pus, and chronic cases, do not, as a rule, demand immediate operation, but may with safety be submitted to **conservative measures** with operation as a last resort if these fail. But if there is any accumulation of pus in the pelvis, nothing less than evacuation will bring about satisfactory results. Of all classes of cases those operated upon for pelvic inflammatory troubles give the least satisfactory results, because breaking up the adhesions and removing an organ or so may not relieve the disease which caused the adhesions and still firmer ones may follow. It is in this class of patients especially in which pelvic massage, passive movements, very hot irrigations, compression over the lower abdomen, and the elevated dorsal posture is of special service, but should be used in a distinctly methodical way. The most important essential in a rational therapy is the complete emptying of the vascular system of the pelvic organs, and this is secured through increase in the abdominal pressure; through acceleration of the recurrent venous flow; through assistance to the flow of lymph by means of gravity; through an elevation of the pelvic organs and the dropping back of the superincumbent organs out of the pelvic cavity; through absolute rest of the diseased organs and their surroundings. The inclination of the pelvis is secured through

elevation of the foot of the bed 15 to 35 cm. Abdominal compression may be made by elastic bandages, adhesive plasters, shot-bags, potters' clay 1 to 5 kilos; vaginal compression is accomplished through inflatable air pessaries, colpeurynters, shot-bags, etc. Pelvic massage is of great assistance in the chronic stages. While the postural treatment with compression may be employed in all forms of plethora of the pelvic organs, its true field is in the treatment of chronic inflammatory exudates in the pelvis, but it should be preceded by a preliminary puncture of the exudate. [W K.]

7.—After using the O'Dwyer method of relieving laryngeal stenosis in 75 cases West is convinced that it is the best means yet at our command for the needed mechanical treatment of these cases. Of this number 73 were cases of laryngeal diphtheria; in 2 the dyspnea was due to laryngitis following measles, and in one to obstruction due to erysipelas. The mortality was 45½% and was the greatest under 2 years; beyond that, age did not seem to affect the mortality. It is highly important that the operation should be brief in duration, that there should be care as to bruising the tissues, and that it should be performed as promptly as possible after the dyspnea becomes great. The average time of leaving the tube in position in the cases which recovered was 6 days, and the best method of feeding during this period is with a nursing bottle which may be used with large as well as small children. The apparently great mortality must not be regarded as a serious objection when one takes into consideration the almost hopeless condition of the cases treated; also the great relief from suffering afforded even to those who did not recover must not be forgotten. In conclusion West says that no professional work he does affords him greater satisfaction than the successful relief of a case of laryngeal stenosis by intubation, and nothing provokes a deeper longing for "a better way" than a fatal result in spite of it. [W K.]

Wiener klinische Wochenschrift.

June 7, 1900. [13. Jahrg., No. 23.]

1. Knowledge of Emboli in the Pulmonary Artery. DRASCHE.
2. Operative Dislocation of the Thyroid According to Wöfler. JOSEPH PREINDLSBERGER.
3. A Case of Extrauterine Pregnancy. HANS HOCK.
4. Hedonal, a Hypnotic of the Urethan Group. ARTHUR SCHÜLLER.

1.—Drasche reports the case of a woman of 63 who entered the hospital with symptoms of heart-disease. A short time after admission she was suddenly taken with symptoms of asphyxia. There was extreme cyanosis, twitching of the muscles of the face, rolling of the eyeballs, loss of consciousness and convulsions. Death followed 15 hours later. At the necropsy a **thrombus** was found in the main trunk of the **pulmonary artery**. The thrombus was 3 cm. in circumference and 4 cm. in length. It divided into a branch which extended into the right pulmonary, obstructing it completely, and a branch 1½ cm. in circumference which extended into the left pulmonary. The thrombi were of dark brown color. The right iliac vein was also filled with a blackish red clot which extended to the vena cava. It is believed that the thrombus originally formed in the iliac vein and that an embolus was carried to the pulmonary artery which gave rise to thrombosis. [M P T.]

2.—Dislocation of the thyroid is the name which Wöfler has given to an operation which he performs in cases in which it is impossible to completely extirpate the thyroid gland for any reason. The thyroid is freed from its bed and is fastened usually in a higher position beneath the skin and the superficial muscles. The indications for this operation are thought to be: recurrence of thyroid growths in which extirpation cannot be carried out without danger of cachexia, though symptoms of compression may be present; and bilateral compression of the trachea by both sides of the gland. An operation is reported which was undertaken for the latter indication in a girl of 15. Wöfler's operation was modified by the ligation of the superior thyroid arteries. The result was in every way satisfactory. [M B T.]

3.—Hock reports a case of **ectopic gestation** peculiarly

interesting because of the long duration of the condition before it was operated upon. The patient, aged 31, had menstruated last on March 9, 1898. The operation was on February 18, 1900. The weight of the entire mass removed was 4,460 g.; of the fetus, 2,710 g. So much trouble was experienced through intestinal obstruction following the operation that a second operation was proposed, but the patient would not permit this; therefore irrigation of the small intestine with the patient in the knee-elbow position was tried with the result that the fecal masses were broken up after enduring for 3 weeks. The patient convalesced rapidly after this and left the hospital on April 16. [W K.]

4.—**Hedonal** is methyl propyl-carbinol-urethan, and in doses of 1.5 grams (22½ grains), given 1½ hours after the evening meal, is a good hypnotic. [D R.]

June 14, 1900 [13. Jahrg., No. 24.]

1. Agglutination Experiments with the Blood of Mother and Fetus. JOSEPH HALBAN.
2. The Knowledge of Actinomyces Fungus. CARL STERNBERG.
3. An Anaerobic Streptococcus. CARL STERNBERG.
4. Bathing the Newborn. H. KOWARSKI.

1.—Halban has tested the **agglutinating action of maternal and fetal blood**. The latter was obtained from the placental end of the cord; the former, from that discharged by the uterus after the detachment of the placenta. He found that the agglutinating properties of the fetal blood were not dependent upon those of the mother. The action of the maternal blood serum and the fetal blood-serum of one case on the blood of another case was tested. Out of 14 cases the maternal blood agglutinated 6 times strongly, 4 times feebly, and 4 times not at all. The infantile blood agglutinated twice strongly, 3 times feebly, and 9 times not at all. The experiments were modified in various ways, but all seemed to show that there was a difference in the content of agglutinins, as well as of hemolysins, on the part of the maternal and the fetal blood. That there is a chemical difference between the blood of the mother and that of the fetal circulation had been proved before. The latter is richer in salts, particularly in sodium, and the freezing point is higher. The differences found by the author must now be added to the facts already known. The discovery that the maternal blood often contains agglutinins, while the fetal blood does not, shows that not all the albuminous substances are taken up by the chorionic epithelium. The agglutinins of the human blood which are capable of agglutinating the red blood-corpuscles of other individuals have been designated by Ehrlich and Morgenroth as isoagglutinins, and the author terms those isoagglutinins which are normally present in the blood and are not produced by artificial means **idioisoagglutinins**. As to the source of the idioisoagglutinins, Halban does not think that they are produced by the continuous absorption of bacterial products, as has been maintained, but holds that they are simply a property normally belonging to the albuminous substances—perhaps the globins—of human blood. [D R.]

2.—In 3 cases of typical **actinomycosis** in man Sternberg succeeded in cultivating, chiefly by anaerobic methods, a fungus growing in the form of small yellowish granules which resembled those found in actinomycotic pus. In the cultures the organisms presented the same forms as in the actinomycoset, but injection into animals only produced abscesses—never the typical roset appearances. Various authors have described actinomycetes like fungi, differing somewhat in their cultural and biologic properties, and Sternberg concludes that **human actinomycosis is due to at least two organisms**, differing culturally and biologically, although the lesions produced are both clinically and anatomically identical. [D R.]

3.—The same author describes an **anaerobic streptococcus** found in the pus from a case of actinomycosis of the lung. [D R.]

4.—From a comparative study between newborn infants bathed every day or every other day, and infants not bathed at all, Kowarski concludes that there is **no harm in daily bathing**. He paid particular attention to the effect on the umbilical cord and the temperature. [D R.]

June 21, 1900. [13. Jahrg., No. 25.]

1. Arterial Sclerosis in the Aged. FRIEDRICH FRIEDMANN.
2. Radiographic Behavior of Pathologic Processes in the Thoracic Aorta. HOLZKNECHT.
3. Depression of the Thorax in Metal Spinners. M. STERNBERG.
4. A New Medicine for the Treatment of Phthisis. JULIUS POLLAK.

1.—Friedmann has studied the cardiac auscultatory signs ascertainable over the back, and finds that the valvular sounds vary in position with the age of the patients. The point of **maximum intensity**, located in the **left inter-scapular space**, moves downward with advancing age. In **arteriosclerosis** the sounds are loudest on a line joining the angle of the left scapula and the seventh dorsal spine. [D.R.]

3.—Sternberg describes a peculiar **malformation** of the right side of the **chest** in **metal spinners**. Below the fifth rib the chest is pressed inward in front and laterally, and forced outward posteriorly. The right nipple is lower than the left. [D.R.]

4.—Fersan is an iron-preparation obtained from the red cells of fresh blood of cattle; chemically it is a ferruginous paranucleoprotein. The author has used it in 50 **phthisical patients** and has found that it produced a speedy increase in the hemoglobin contents of the blood and of the body-weight. It was given as follows: A coffeespoonful was mixed in a tumbler with a little water, and the tumbler then filled with cold milk. This was taken thrice daily, one-half hour before the meal, and corresponds to a daily dose of from 7 to 8 grains fersan. [D.R.]

June 28, 1900. [13. Jahrg., No. 26.]

1. An Approved Tracheal Canula. R. GERSUNG.
2. Suture Treatment of Luxation of the Acromial End of the Clavicle, and of Fractures of the Nasal Bones. KONRAD BÜDINGER.
3. A Patient with Wandering Gallstone. ROBERT PORGES.

1.—Gersung recommends a **tracheotomy tube** of funnel shape and claims for it the following advantages. Its larger caliber permits freer respiration and its tracheal end never comes in contact with the mucous membranes. The widened tracheal part of the tube fills the lumen of the trachea completely and prevents the entrance of any blood or wound secretion into the tube. A disadvantage is that a larger opening into the trachea is necessary. Gersung claims that pressure necrosis never results after the use of this tube. The disadvantages of the ordinary tracheotomy tubes are that while they bend requires so much room in the trachea their caliber is usually quite small. The tube often presses against the mucosa of the larynx and by inaccurate adjustment is likely to cause pressure necrosis of the soft parts. [M.B.T.]

2.—Büdinger believes **suture** in case of **luxation** of the **acromial end** of the **clavicle** and in certain fractures of the **nasal bones** as quite as necessary as the suture for fracture of the patella or olecranon. He finds that luxations of the acromial end of the clavicle have been estimated to make up from 2 to 6% of all luxations, and the function of the arm is very often considerably disturbed. Often this disturbance of function does not appear until some time after the injury. A special disadvantage is that the end of the bone is very prominent and is pressed upon with laboring men who are accustomed to carry weights upon their shoulders. A case is reported in which suture was successfully performed. Suture for fracture of the nasal bones is recommended in cases in which a longitudinal break is combined with a transverse fracture of the bones. With displacement to the side reposition is almost impossible without operation. The incision in a median line leaves a very insignificant scar which tends to disappear and is never very noticeable. [M.B.T.]

3.—A woman of 47 had had a fistula of the upper part of the thigh for 1½ years. For 20 years she had suffered from pain in the stomach, and gallstone colic, and she had repeatedly taken Carlsbad cure. A painful tumor appeared in the region of the trochanter and produced a considerable deformity. After some time it ruptured spontaneously and

a large mass of pus escaped. The diagnoses of tuberculosis, actinomycosis and syphilis were discussed. Two fistulas remained from which the pus escaped. An operation was performed and on splitting open the fistula it was found to lead into a network of canals in the upper part of the thigh with numerous pockets. In the lower part was a **pouch containing** a large number of **gallstones**. This pocket reached to the **middle of the thigh**. Numerous incisions were made, a drainage tube was inserted, and the cavity was packed with iodoform gauze. A very good recovery followed. Chemical examination showed the stones to be composed of cholesterol and carbonates. The entire weight of the stones removed was 9.4 gm. It is thought that the gallbladder became fixed by inflammatory adhesions, and when it perforated the stones worked their way along down the back under the fascia dorsiolumbalis. [M.B.T.]

4. After-Treatment in Operations on the Eyeball. G. GUTMANN.
5. Typhus Abdominalis. DR. RUMPF.
6. The Term Stomach dilation in the German Literature since 1875. ARTHUR HESSE.

1.—In regard to **displacements of the uterus** Veit is of the opinion that every gynecologist should have full knowledge of therapeutic treatment; and, usually, this should be tried before there is resort to surgical measures; but he admits that the "reception-hour" treatment is lessening as operative gynecology seeks to win the field. Experience has also taught that the sensitive organization of many women will not bear repeated "local therapy," and that in such cases operative treatment is preferable. In the various forms of **inflammation** it is essential to ascertain the etiology of the case in order to treat it to the best advantage. We must understand the hygienic rules which lessen the danger of gonorrheal or other infection, and know how to treat without injuring the patient. [W.K.]

2.—While the mosquito may be the chief agent in the transmission of **malaria**, the **mosquito theory**, according to Grawitz, does not explain the whole epidemiology of the disease. He illustrates by curves that, in the Prussian army, the incidence of the disease rises from the month of March and reaches its height in June, at a time of the year when mosquito-bites must be very rare. Moreover, there has been a marked reduction in the morbidity in the last few years, apparently coincident with the regulation of the water-supply, and he implies that the drinking water may convey the disease. [D.R.]

3.—Mendel states that in the past 8 years 9 patients have come to Hirschberg's clinic who had lost an eye by an operation for **cataract** and who had developed cataract in the other eye. The unfortunate results of the first operation make the success of a second operation extremely important. A thorough aseptic preparation is the chief condition of success. The tear apparatus is a common source of infection, and if any inflammatory condition exists it must be thoroughly treated. The thorough antiseptic treatment of the nose for some time before the operation is also advised. In addition to this the lids must be carefully prepared. General anesthesia permits of much more thorough asepsis and is advisable in these cases. Preparatory iridectomy is also advised and the operation for cataract is undertaken 3 weeks later. In the 9 cases mentioned the cataract operation was performed on the second eye with perfect success. [M.B.T.]

5.—Rumpf's article treats of **typhoid fever** in a general way, and recapitulates the more recent contributions to the knowledge of the disease. [D.R.]

6.—Hesse adopts the views of Kuttner regarding **gastric atony** and **gastrectasia**. Under atony is to be understood that condition in which, with a normal size of the stomach, there is an impairment of the tone of the musculature of the organ. In consequence of this, the stomach wall is abnormally stretched by the food. When empty the organ returns

to its natural size. Gastrectasia implies a **permanent dilatation** of the stomach, demonstrable also when it is empty, as well as an insufficient evacuation of the organ, so that even in the fasting stomach more or less stagnating food remains. The exact diagnosis of dilatation of the stomach is based upon the simultaneous demonstration of enlargement of the organ and disturbance of its motility. [D.R.]

3. A Case of Complete Visceral Inversion, Combined with Dissecting Aneurysm of the Aorta. ARTUR BARBO.
4. Anatomical Relations of the Cerebellum to the Rest of the Nervous System, and the Significance of the Same for the Understanding of the Symptomatology and Diagnosis of Cerebellar Diseases. LUDWIG BRUNS.
5. The Prognosis of Glycosuria and of Diabetes. FELIX HIRSCHFELD.

3.—Barbo reports a case of complete **transposition of the viscera** in connection with an extensive dissecting aneurysm of the aorta. As to the frequency of the occurrence of transposition of the viscera, he states that this is the only case which has been found in 676 complete necropsies which have been made at the Pforzheim Hospital since 1878. As a point of interest he mentions that the patient was right-handed, and he finds by an investigation of other cases of the kind that transposition of the viscera is not usually accompanied with left handedness. [M.B.T.]

4.—The **cerebellum** is connected with the cord and with the upper brain in such a way that it constitutes the vertex of a reflex arc to which centripetal fibers go, and from which centrifugal fibers descend. The **centripetal pathways** are the direct cerebellar tract and Gower's tract. They probably convey sensations from the muscles and joints—sensations that constitute the so-called positional sense. It is probable, also, according to Bruns, that the cerebellum receives some fibers carrying touch and pressure sensations—if not from the skin itself, then from the subcutaneous tissues. The **centrifugal pathways** have only recently been discovered. Motor fibers pass from the tegmental nuclei of the cerebellum to Deiter's nuclei. From the latter two motor pathways arise. One passes to the oblongata and the spinal cord by way of the restiform body; the other passes to the floor of the fourth ventricle and to the oculomotor and abducens nuclei. These different tracts complete the **spinobulbo-cerebellar reflex arc**. The connections between the cerebellum and the cerebrum are not well known. One, passing from the corpus dentatum of the cerebellum to the red nucleus of the opposite side, has been definitely determined. Thence it is continued to the optic thalamus, and possibly to the motor area of the brain. Others, passing from the temporo-occipital and the frontal cortex to the cerebellar hemispheres, have also been established. The most important connections of the cerebrum may be summed up as follows: The cortex, especially that of the vermes, constitutes the vertex of a reflex arc, to which pass sensory excitations by way of the posterior columns, direct cerebellar

tracts, and Gower's tract, and by way of the vestibular nerves. By means of these the brain receives information concerning the position of the limbs and head, of the body in space, and of the tension of the muscles, joints, etc. In response to this information, the cerebellum regulates the position and movement of the limbs, head, trunk, eyes, etc., by way of sagittal fibers passing to the tegmental nuclei, thence by fibers passing to the Deiter's nuclei, thence by way of the posterior longitudinal bundle and the oculomotor nuclei to the restiform body, and finally, along the anterior and anteriorolateral tracts of the cord into the anterior horns. This reflex arc generally acts automatically—subconsciously—but it is connected with the brain, and the various data may in that way come within the limits of consciousness. In **diseases of the cerebellum** the most constant symptoms are: (1) disturbances in the equilibrium, so-called cerebellar ataxia; (2) vertigo; (3) changes in the position of the visual axes, nystagmus, and at times paralysis of ocular muscles; (4) weakness in the muscles, which, in unilateral lesions, is probably on the side of the lesion. The most important are ataxia and vertigo. The ataxia is variable in character. It is produced chiefly by destructive lesions of the vermes, but also by lesions in other situations which may interfere with the reflex arc. The ataxia cannot be considered a pathognomonic symptom of cerebellar lesions, as the same form of ataxia is observed in Friedreich's disease, and in certain diseases of the oblongata, pons, and quadrigeminal bodies; likewise, also, in tumors of the frontal lobes. It is probable that, in lesions of other parts of the brain giving rise to ataxia, the result is due to interference with pathways connected with the cerebellum. [D.R.]

5.—The author's conclusions are as follows: The prognosis in the milder forms of **diabetes** is more favorable than has been the prevalent view. He believes that a relative cure (*i. e.*, absence of sugar, with a diet containing 200 grams of carbohydrates) may be expected when in the beginning of the disease from 80 to 85% of the ingested carbohydrates are consumed. He has observed the assimilation of carbohydrates getting less after influenza, after peculiar colicky attacks (pancreatic?), and in an especially high degree after gangrene and furunculosis. A change of the condition for the worse is sometimes signalized by an increase, and an improvement by a decrease, in the quantity of urine. At times an increase in body-weight coincides with an increase in the glycosuria, which subsides with a restriction in diet. The cardiac debility sometimes observed in diabetes is favorably influenced by an antidiabetic diet, with diminution, but not complete exclusion, of the carbohydrates. [D.R.]

1. The Present Position of Bacteriology. BAUMGARTEN.
2. A Constant Bacteriologic Condition in Scarlet Fever. BAGINSKY and SOMMERFELD.
3. The Treatment of Phthisis in Hospitals and Among the Poor. BURGHART.
4. Is Multiplication of the Blood Corpuscles at High Altitudes Reasonable or Not? GOTSTEIN and SCHRÖDER.
5. Accumulation of Kidney-Stones. SPIEGEL.
6. Brain Anatomy and Psychology. L. EDINGER.
7. Aspirin Treatment. ZIMMERMANN.
8. Experience with Aspirin in Private Practice. A. DENGEL.
9. Cause and Local Beginning of Phthisis. AUFRECHT.

3.—Burghart describes the **symptomatic treatment of tuberculosis** as carried out in the clinic of Von Leyden in Berlin. **Fever** is combated with rest in bed and cold ablutions; occasionally by the use of pyramidon, quinin, or phenacetin. The **night-sweats** are usually controlled by means of spongings with water, aromatic vinegar, or water containing a little citric or tartaric acid; likewise by a 1 to 2% menthol solution or by formalin alcohol solutions containing 10% of formalin and from 3 to 4% of peppermint oil. Atropin is not employed. If **diarrhea** exists and cannot be relieved by careful diet, compresses of warm oil and cotton are employed, or bismuth and tincture of opium, tannalbin, tannigen, or dermatol. If there is tenesmus, opium suppositories are given. In bad cases creosote seems to be of value or starch clysters. **Pleuritic pains** are relieved by warm applications or mustard plasters, or by fixa-

tion of the chest in a felt splint. In bad cases morphin or one of its succedanea is given. Nothing new is recommended for **hemorrhage**. He has not found gelatin injections superior to other forms of treatment. Injections of salt solution containing from 1½ to 2% of salt have given satisfactory results. The **prophylaxis** of phthisis is touched upon and the usual measures described—hardening the system of the predisposed, care in the domiciliary prophylaxis, etc. The general health of tuberculous patients should be improved by outdoor life, abundant sleep, and an adequate diet, a mixed diet with plenty of meat being the best. The author is a great believer in the value of sugar—cane or beet sugar—as a food, and gives as much as 200 grams (6½ ounces) per day. The use of alcohol in small quantities is permitted, but is not considered indispensable. [D.R.]

4.—Some additional experiments showing that the Thoma-Zeiss apparatus is under the influence of the atmospheric pressure, and that the higher **blood-counts in mountainous elevations** are due to such external physical conditions. [D.R.]

5.—Spiegel has examined a series of stones removed from the kidneys and ureter by Professor Israel, to determine with regard to their composition. Out of 44 stones he found only 6 which were homogeneous in structure. The others were composed of concentric layers of various salts. CaCO_3 was found in 60% of the layers examined. The phosphates were next most frequently found, then the oxalates and urates; the various other constituents were comparatively rare. The oxalates were always found in connection with the urine with an acid reaction and in all cases in which uric acid, urates, or xanthin were important constituents, anuria was present. [M.B.T.]

6.—Edinger's article is of great interest. It pictures the achievements of **brain anatomy and physiology** and the rather barren results of modern **psychology** during the 19th century. Comparative studies seem to show that consciousness is of less importance than has been believed, and that many of the acts of animals, and possibly of human beings, which are considered as indicating the conscious exercise of the will, are in their ultimate nature reflex. The article does not lend itself to abstracting. [D.R.]

7 and 8.—Favorable reports on the use of **aspirin** in rheumatism and neuralgia. [D.R.]

4. The Present Position of Bacteriology.
5. A Constant Bacteriologic Condition in Scarlet Fever. BAGINSKY and SOMMERFELD.
6. The Treatment of Phthisis in the Hospital and in Army Practice. BURGHART.

2.—A man of 44 had first noticed an increase in the size of his abdomen 2 years previously. Recently this increase had become much more marked until he was unable to follow his business. The abdomen was uniformly firmly distended, and to the left below the umbilicus there was decided resistance and many nodules could be felt. It was dull on percussion everywhere. The diagnosis was questionable, whether it was a nodular form of tuberculosis of the peritoneum, with adhesions and encapsulated exudate, or some form of rapidly growing tumor. A median incision was made from the ensiform to the middle between the umbilicus and symphysis. On opening the peritoneal cavity no omentum or intestines appeared. They were entirely pressed upward into a very small space. A yellowish tumor lay directly below the parietal layer of the peritoneum. This was extirpated with considerable difficulty as it was adherent to many important abdominal structures. The peritoneum was independently sutured and the wound cavity was packed with gauze to avoid as far as possible the dangers of hemorrhage and infection. After the operation the patient recovered readily from collapse and remained without rise of temperature. Eight days after operation, however, he died sud-

denly of collapse. The necropsy revealed no cause of death. It was without doubt due to the sudden change in interabdominal pressure, as is often the case with such large intra-peritoneal growths. The tumor proved to be a fibrolipoma weighing 22 pounds. König states that 4 years ago 30 cases of such **retroperitoneal fatty tumors** had been collected and since that time but few have been reported. [M.B.T.]

4.—A resume of the present status of **bacteriology**, in which the author declares his adhesion to Ehrlich's lateral-chain theory of immunity and in which he reiterates his non-belief in the existence of bactericidal substances in the blood. [D.R.]

5.—Baginsky and Sommerfeld, from the study of 42 cases of **scarlet fever**, draw the following conclusions: (1) In all cases of scarlatinous angina it is possible to find **streptococci**, sometimes in pure culture, sometimes accompanied by other cocci. (2) In all the fatal cases of scarlet fever examined by them (42) they found in the organs, in the blood, and in the bone marrow, a streptococcus—from which it is fair to conclude that the streptococcus is constant in scarlet fever. In its morphologic, cultural, and biologic behavior the streptococcus is like that described by other authors. It cannot be differentiated by the usual culture methods. (4) The streptococcus is of a variable virulence, and its virulence can be increased by passage through animals. It elaborates a toxin which it gives up to the culture medium. (5) It was impossible to discover any specific properties. (6) The constant presence of the streptococcus in fatal cases of scarlet fever gives it an importance in the scarlet fever process. (7) All the phenomena of scarlet fever can be readily deduced from a distribution of the streptococci in the organs (infection) and the toxicity of its metabolic products (intoxication). [D.R.]

6.—Inhalations of various substances are of value in local tuberculous lesions, and the author recommends **formalin**, beginning with the ¼ solution inhaled through a mask similar to that used in chloroformization. He has no faith in specifics, but he believes that creasote and its various preparations are of value. Creasote is best given in gelatin capsules, combined, in the capsule, with cod-liver oil. [D.R.]

4. Diagnosis of Functional Disorders of the Kidney. CASPER and RICHTER.
5. The Pathology of Morbid Tumors. O. ISRAEL.

2.—A resume of the methods employed for demonstrating **tubercle bacilli** by experimentation on animals. [D.R.]

3.—A study in **metabolism** on 2 cases of **diabetes insipidus**—a man of 47, and a girl of 14 years. It was found that the patients did not eliminate more water in the urine than they ingested; moreover, the insensible perspiration was practically normal, contrary to the statements of some of the older writers. A study of the albumin metabolism showed that in one case there was a retention, and in the other a loss. Digestive functions were good, although the appetite in the young girl was somewhat diminished. The acidity of the urine was high. The elimination of P_2O_5 in the feces was normal. In the urine there was a retention on the part of the man, and a loss of P_2O_5 on that of the girl. The chlorin studies were not sufficient to enable conclusions to be drawn. [D.R.]

4.—It is important in many cases to determine the **functional capacity of the kidneys**, particularly of the two kidneys separate y. French investigators have done this by obtaining the urine excreted in 24 hours from each organ by ureteral catheterization. Casper and Richter, however, found that during a period of from 30 to 60 minutes the two kidneys eliminated almost absolutely the same amount of solid constituents, and that it was not necessary to retain the catheters longer than this. One of the best indices of the functional capacity was the elimination of sugar after the administration of phloridzin. The sugar, since it is made in the kidney, is a token of the functional power of the renal

cells. The diseased kidney secretes a much smaller amount than the normal organ. In advanced disease the elimination of sugar from the diseased organ may be practically nil. If both kidneys are diseased, the differences are more or less wiped out. The elimination of sugar and of urea, and the molecular concentration, with few exceptions, run parallel; but the sugar elimination after phloridzin injection is the most delicate of the three agents for testing the functional power of the kidney. [D.R.]

Deutsche medicinische Wochenschrift.

July 5, 1900. [26. Jahrg., No. 27.]

1. Enucleation and Substituted Methods, with Especial Review of Sympathetic Ophthalmia. H. SCHMIDT-RIMPLER.
2. Our Knowledge of Serums. ALBERT SCHÜTZE.
3. Experience with a Substitute of Morphia. L. NIED.
4. Subphrenic Abscess after Pancreas Suppuration of Traumatic Origin. WILHELM STROHMAYER.
5. My Experiences with Light Therapy. H. STREBEL.

1.—Schmidt-Rimpler, in speaking of the three operations on the eye, **enucleation**, **evisceration** and **neurectomy** **optociliaris**, prefers almost without exception the first when either of the three is indicated. The wound following enucleation heals more rapidly, in recent injury cases, in about half the time required after evisceration. In cases where the sympathetic inflammation had already set in, some very satisfactory results were secured by the enucleation; in 4 out of 10 cases the eye recovered and was capable of visual activity. In cases of recent injury he removes the injured eye when the sight has been destroyed and signs of sympathetic irritation begin to appear in the second eye. In cases where the primarily injured eye still retains considerable sight more conservatism should be practised. He ends his article by reporting 4 cases. [G.B.W.]

2.—Schütze first reviews previous work concerning the dissolving effect of various serums, mentioning the most important details that have been accomplished in this work, particularly the fact that serums which kill epithelium have been produced in guineapigs. This and other facts have made it seem reasonable that by working upon this line it may prove possible to provide a serum which will be effective against malignant growths. He reports his own results in the production of an antihemolytic serum. He found that after injecting rabbits with the blood of guineapigs the serum of the rabbit gradually acquired a marked hemolytic power against the serum of guineapigs. If now the serum of the rabbit were injected into the guineapig in small doses there was gradually produced some substance which prevented the hemolysis of the guineapig's blood by the rabbit's serum; hence some antiserum had been produced. Its production was due apparently to the so-called "intermediate bodies" in the hemolytic serum, the "end-bodies" playing apparently no role in the production of the antihemolytic substances. He made attempts to produce a liver and kidney serum, analogous to the hemolytic serum, by injecting emulsions of normal livers, and kidneys of guineapigs into rabbits. The results were negative. But, as stated, this does not show that such a thing is impossible. Wassermann has previously demonstrated that similar results may be produced with the serum of certain animals, while that of other animals has no effect. [D.L.E.]

3.—Nied reports a series of cases to demonstrate the good effects of **heroin**. They were chiefly pulmonary tuberculosis, bronchitis, pleurisy, asthma, and Bright's disease with marked dyspnea. [D.L.E.]

4.—In the case of **traumatic suppuration of the pancreas** reported by Strohmayer the characteristic symptoms of pancreatic disease were lacking, in that there was no fatty diarrhea and no diabetes. The symptoms present were pain in the upper abdomen, nausea, vomiting, loss of appetite, irregularity in the bowel movements, abdominal distention, general loss of strength, and at times icterus. At the postmortem pus was found in the right pleural cavity which communicated by a small opening with a subphrenic abscess. Abscess of the head of the pancreas was also found. [G.B.W.]

5.—Strebel gives a somewhat lengthy account of his ex-

perience with **light-baths**, having apparently found them useful in any form of disease in which they were tried. He mentioned especially that they were valuable in kidney and heart-disease, in diabetes, and obesity. It had particularly good effects in arteriosclerosis and fatty heart. Probably the chief effect was produced by the sweats in most cases. It is, of course, quite possible that the baths may exercise some influence upon metabolism. As to whether this is directly due to the action of the light and heat, or indirectly the result of the increased sweating, is uncertain. [D.L.E.]

Centralblatt für innere Medicin.

June 30, 1900.

1. What Clinical Importance may be Attributed to the Ephemeral Rises of Temperature which Occur on the Day of Admission of Patients to Hospital? E. FROMM.

1.—It is often observed that the **temperature rises** somewhat on the day of admission to hospital and then sinks—a phenomenon which is frequently attributed to the nervous excitement incident to removal to the hospital. Fromm, at Strauss's suggestion, looked over the records of 100 cases in which this rise of temperature occurred, with the special purpose of seeing whether it had any relation to phthisis, since the temperature in phthisical patients is very easily influenced. He found that, with the exception of febrile rheumatism and gastrointestinal disturbances, very few of the cases occurred with any other condition than diseases of the respiratory apparatus. The latter were chiefly phthisis; in fewer instances, bronchitis and pleurisy. The 2 latter diseases might readily have been of tuberculous nature, and hence he decides that these temporary rises in temperature, while not by any means positively indicative of phthisis, are, in the presence of other suspicious conditions, decidedly suggestive of phthisis, and are to a certain extent a guide in diagnosis. [D.L.E.]

July 7, 1900.

1. Some Unfavorable Experiences in the Subcutaneous Use of Gelatin in the Treatment of Hemorrhage. MAX FREUDWEILER.

1.—Two cases of **hemorrhagic nephritis** are reported in which gelatin was used with the thought that it might control the loss of blood through the kidneys. Instead of this, the result was a very marked increase of the albumin, a reduction of the amount of urine secreted, an increase in the amount of casts, and in both cases a marked hemoglobinuria. The symptoms appeared so quickly after the use of the gelatin that it was decided that it was the result of its use. Another case is referred to in which uremia came on directly after the use of the gelatin, and we are reminded that Lancereaux himself has always stated that gelatin is not a harmless substance. [D.L.E.]

Centralblatt für Gynäkologie.

July 7, 1900.

1. Upon Bruns' Ointment as Material for Dressing Wounds. A. DÖDERLEIN.
2. Artificial Abortion: Its Indications and Its Execution with Certainty and Without Danger. OEHLISCHLAGER.

1.—Döderlein highly recommends Bruns' **airol ointment** for the dressing of aseptic wounds. He has used it in operations upon the perineum, in Alexander-Adams operation, and especially in laparotomies. After closing the incision with proper sutures, he covers it with a rather thick and broad layer of the ointment, covers that with gauze strips, and then strips of adhesive plaster, and does not touch it until the twenty-first day, when he removes gauze, ointment, and sutures. With this method, out of 400 cases, 356, or about 90%, healed satisfactorily. In the others, he ascribes the stitch-abscesses or suppuration to the condition of the patients, who had pyosalpinx, suppurating cystitis, or tuberculosis. He values the ointment, not for any antiseptic qualities, but for its hygroscopic, drying, immovable, and hermetically sealing characteristics. [W.K.]

2.—Since it has long been an established fact that under certain conditions **artificial abortion** is demanded and is justifiable, Oehlschlager believes that the earlier it is produced the less dangerous to the patient and the more easily its effects are overcome. For this purpose he introduces a curved metallic catheter into the uterus to the fundus, then passing a syringe of the same caliber, syringes the uterine cavity, especially near the ovary, with 3 to 4 g. of iodine tincture. Afterwards he places a tampon in the vagina to protect the mucous membrane from being irritated by any outflowing iodine. One application usually suffices; if not, it may be repeated. The peculiarities of the iodine are that it quickly penetrates the tissues, destroying fetal life; that its high antiseptic powers ward off injurious effects, and it stimulates the activity of labor-pains in the uterus. [w.k.]

July 14, 1900.

1. Healing of Rectal Prolapse by Restoration of the Pelvic Floor. OTT.

2. Medullary Narcosis in Obstetrics. O. KREIS.

1.—Ott holds that **rectal prolapse** is usually due to loss of equilibrium in the pelvic organs caused by some weakening or injury of the muscles of the pelvic floor; hence any true or efficient remedy must be directed to the restoration of the pelvic floor, and thus all the neighboring organs may be properly supported. He reports a case treated on this principle, first reducing the prolapsed rectum, and then continuing the operation as for complete laceration of the perineum. Convalescence was uninterrupted and the cure complete. [w.k.]

2.—Tuffier and Bier both conducted experiments in using **injections of cocaine in the spinal cord** to produce insensibility of the body while undergoing operations either upon the bones or the soft tissues. And Tuffier's report of the success of these experiments, the loss of sensation involving little or no disagreeable accompaniments, led Bumm and his assistant Kreis to conduct a series of experiments testing its use in obstetrics. Kreis gives a detailed report of 6 obstetric cases. The injection of the cocaine was made between the fourth and fifth lumbar vertebra and in 5 to 10 minutes produced complete analgesia of the lower part of the body, while the control of the muscular movements appeared to remain complete. Although the patient was conscious of no suffering, the activity of the labor-pains continued, and the motility of the uterus remained undisturbed. While the procedure may not be adapted to all cases, Kreis thinks it is valuable for patients in whom the presence of some disease of heart or lungs makes the use of chloroform full of danger. [w.k.]

July 21, 1900.

1. Reply to Ballin "Upon the Treatment of the Umbilical Stump According to Martin." A. RIECK.

2. Porro-Cesarean Section for Excessively Large Dead Child. H. RIEDINGER.

3. Malformation of the Female Genitalia. KREISCH.

1.—Rieck considers Martin's method of **treating the umbilical cord** by a combination of ligating and cauterization by means of silk sutures and a cautery as a decided advance. Scientific investigation will confirm this view, since it brings healing of the stump quickly, avoids any hemorrhage with the greatest certainty, and furnishes simple and agreeable conditions for the after-treatment. [w.k.]

2.—Riedinger reports the case of a primipara of 30, married 7 years, who was delivered by **Cesarean section** after a pregnancy of 300 days, the child being dead 9 days before delivery. He first made every effort to deliver the woman by the use of the cranioclast and forceps, but without avail, and in order to save the life of the mother was obliged to perform Cesarean section. The impossibility of delivery through the normal route was due to the extraordinary size of the child which, without the brain and apex of the skull, weighed 5,750 g., and measured in length 64 cm., being the largest he had ever observed in 26 years of obstetric practice in and out of the hospital. [w.k.]

3.—Kreisch reports the case of a young woman coming under his observation, who, although the external genital organs were perfectly developed, had no vagina, and a careful examination under anesthetic showed no trace of uterus, ovaries or tubes. [w.k.]

Neurologisches Centralblatt.

July 1, 1900. [19. Jahrg., No. 13.]

1. A Contribution to the Knowledge of the Earliest Stages of Multiple Neuritis. S. POPOFF.

2. Psychological Observations in a Case of Gas Poisoning. WEYGANDT.

3. An Anomaly of the External Ear. C. KLIENEBERGER.

1.—It has been generally supposed that the **earliest symptoms of multiple neuritis** were the paresthesia or the paresis complained of by the patient. There are, however, objective symptoms that probably precede by a considerable period these purely subjective disturbances, which are extremely important for the reason that it is still possible by the withdrawal of the toxic influence to prevent the occurrence of the disease in its developed form. Popoff believes that by means of careful electrical measurements it is possible to detect them. Of course, the opportunity is not frequently presented. He was led to this opinion by observations upon a patient who for a number of years had indulged to excess in alcohol, but was apparently perfectly well, with the exception of a pronounced ataxia of the hands and feet. An electrical examination showed that the interosseous muscles 1 to 4 in the left hand did not contract to the faradic current and, although they gave the normal contraction, their response to galvanism was diminished. Other patients in the hospital were then examined. A man of 68, who had had a slight apoplectic attack involving the left side, and who had always been an alcoholic, had ataxia in both legs, more pronounced on the left side and in the left arm. There was pain in both calves, some disturbances in the motion of the fingers, the reflexes were diminished or abolished, and Romberg's symptom was present. Careful measurements showed disturbances in the muscles acting upon the toes and fingers on the left side and in a few of the muscles of the hand on the left side. None of the affected muscles reacted to faradism or only by a sluggish contraction—that is to say—this patient, in addition to his apoplectic condition, suffered from multiple neuritis. The third patient, a man of 40, had had lead-poisoning. He developed a hemiparesis with loss of tactile sense on the left side. There was disturbance in the thenar muscles on the right side, and of the thenar and interosseous on the left side. The case could not be hemiplegia due to cerebral lesion on account of the absence of degeneration of muscle, because the diminution of the response to electricity exceeded the degree of muscular degeneration and because the lesions were symmetric. [J.S.]

2.—Weygandt, having warmed the air and heated the water in a small bath-room with a gas stove, and thereby vitiated the atmosphere to such an extent that neither candle nor lamp would burn in it, undertook to take a bath. He noticed so soon as he entered, severe pulsation in the temples, ringing in the ears, a feeling of anxiety, then dizziness, some irritability; he then recollects going into his sleeping apartment, when he became unconscious. When he awoke he found himself lying upon the floor of his room, there was intense headache, vertigo, but nevertheless a feeling of indifference. He imagined that he had had an epileptic attack and thought of several peculiarities in the character that tended to confirm this diagnosis. He arose, went into another room and again became unconscious. When he awoke he found that he had vomited, there was roaring in the head, and extreme weakness of the muscles. He imagined that he had been poisoned by some preserves, but was nevertheless able when assistance arrived to ask for stimulants and to write to a colleague requesting him to come to his assistance. At the same time he correctly diagnosed his case. The **psychical course** of the condition, therefore, represents a disturbance of the intelligence and motion, then complete unconsciousness. This was followed by amnesia that involved a considerable period previous to the intoxication, that is retrograde amnesia associated with a correct recollection of earlier periods. The poison appears to have been due almost exclusively to **carbonic acid-gas**. [J.S.]

3.—Klieneberger reports the case of a man suffering from general paralysis who presented a curious **anomaly of the ear**, the tip being closely joined to the scalp; otherwise the appearance of the ear was almost normal. It appears, as a result of an investigation upon 450 patients in the insane asylum, to be an exceedingly rare anomaly. [J.S.]

THE MASTER OF MEDICINE AS THE TEACHER
OF MEDICINE.By BAYARD HOLMES, M.D.,
of Chicago, Ill.Professor of the Practice of Surgery in the University of Illinois, and Secretary
of the Association of American Medical Colleges.

In these days of endowments and of great hospitals, great laboratories and "poly-logical" institutes, the teacher as a factor in medical education is apt to be forgotten. This strange socio-psychic phenomenon is brought to mind in this connection by reading a recent article on general American education by a German professor of psychology.¹ He considers the chief and distinguishing characteristic as well as the principal virtue and glory of his education in Germany to have been the masterly superiority of his teachers. His teachers of mathematics were first and above everything else masters and doctors of mathematics; his teachers of Latin were masters of the Latin literature, and his teachers of chemistry were distinguished chemists. Thus in the most elementary class he was under the tutelage of no mere disciplinarian, but in the radiant enthusiasm of a master, a leader and a discoverer. To such superior teachers he attributes the rapid advance of the German boy through science, literature, and philosophy with a gain of one third the time and energy which the American boy expends.

It is certainly true that our colleges and universities are full of professors who hold positions to which they have, by the evidence of work done or mastery attained, no reasonable claim. Professors of Latin are ignorant of anything but the most rudimentary Latin; professors of physics are tyros in a laboratory, and are lost in the mathematics of optics; professors of music are unfit to lead the orchestra of a beer garden. Mere proficiency in Arabic, a knowledge of the language, literature, and history of Arabia may not be the only desirable qualities of a professor of Arabic, but they certainly are essential qualities. Our colleges and universities are full of men who are masters of nothing. They are, many of them, pleasant amateurs, but they are guiltless of grasp or art in their departments.

In only a few of our medical schools has any serious effort been made to teach medicine. When we have in every State of the Union supporting a medical school, such an anatomical institute as that at Berne or at any one of twenty German universities, when each of fifty of our medical schools provides such a physiologic institute as that at Leipzig, and have equipped on the same scale pathology and pharmacology, it will perhaps then be time to talk about thoroughly prepared teachers. It is a source of great satisfaction that Harvard and Johns Hopkins in the East, and Michigan and Minnesota in the West, have such magnificent equipment in laboratories and hospitals. There are other schools following not far behind these. But equipment alone is not enough. The studio does not make the sculptor nor the violin the artist. These laboratories and hospitals must be manned with masters and teachers. There are some most remarkable examples of good teaching in almost every branch of our medical curriculum, and the past records many celebrated and

original lectures. The serious progress of our American medical education is obstructed by poor teachers everywhere. These men hold their positions because they are there and no one can displace them. The students are passive because they know nothing about the subject, or knowing, they are powerless to change.

No effective check is placed on poor teaching or poor teachers, no preferment comes to the good teacher, and no search is made by the university for scholars. When adjunct professors are sought by overworked professors, the weaker rather than the stronger candidate is selected. How many times has this been illustrated in the last ten years! The second place in a department is to be filled. The candidates are assembled. The choice falls upon the senior professor. He chooses the harmless and forceless man because he can never become a rival.

In any good and workable educational system there must be some method by which the ability of educated men to teach medicine can be tested—by which a constant supply of trained teachers can be provided for the medical school. Prof. Osler has suggested the advantages of extramural teaching. This system, so much in use elsewhere, has not been tried to any extent in America. With the growth in hospitals and the great increase in the number of medical students, it must soon be considered. It would put many men as well as many hospitals on trial, and would no doubt discover, if not develop, a lot of good medical teachers.

Our whole system of medical teaching has been too far exclusive, proprietary, and iron-clad. We have a professor of anatomy, instead of several professors of anatomy. The student must attend certain lectures and do certain laboratory work, instead of attaining a required proficiency. He must pass certain professors' examinations, instead of having an opportunity to show his knowledge of medicine in an original work. The whole aim seems to be to train helpless incompetents. There is no teaching or training of strong men in medicine—independent and progressive.

But what can be expected with such faculties as are gotten together. "Like teachers, like pupils." Take a medical college catalog from your table and read of the names of the faculty from dean to diener. Opposite each name write down any contributions made to his science by each professor in turn. Consider the quality of the man's contributions and its influence. Then alone can the sterility of our medical education be explained.

Our system is bad—a survival of the ancient Scotch method. Our teachers are badly chosen on account of the very motive of medical teaching, and were it not for a most remarkably earnest student-body the results would be disastrous. Medicine is so absorbing and inspiring, and our American student is so self-reliant and venturesome, that, given now and then a teacher to set the student a pace, the results of our system become endurable.

If instead of looking at the actual present conditions we look at the progress made in medical education during the past 15 years, we have great reason to rejoice. The danger now lies in arresting this growth because our schools have become big and prosperous. Our progress has been great, but it has just begun. We must insist on adequate equipment in every department. Every college that is worthy of the name must have an institute of anatomy, an institute of physiology, an institute of pathology, a medical library, a hospital

¹ *The Atlantic Monthly*, May, 1900.

of general medicine and a large coordinated faculty. Every man in that faculty ought not only to have earned his position through the mastery of his science which he originally showed by a contribution to its advancement, but he should hold his position by continued contributions and by his ability to lead and inspire students to similar original work. As the time to appoint members of the faculty approaches, the dean should ask what contributions to medicine each applicant for appointment has made for himself or in the names of his students. If no work has been done, the questions may be asked: Has the man stopped growing? Is he working under dwarfing conditions? Can this unfruitfulness be otherwise satisfactorily explained? Let the faculty be composed of well-equipped and growing men, let each teacher have freedom and each student have guidance and example, and our students will bring honor upon our profession and they will enrich our literature.

THE TEACHING OF PHYSIOLOGY.

By WILLIAM TOWNSEND PORTER, M.D.,

of Boston, Mass.

Associate Professor of Physiology in the Harvard Medical School.

To the physician the study of physiology is of use largely because it creates a habit of thought essential to the highest professional success. Physiology is a *rational* science. Its problems require the scientific method. They demand the precise statement of the question in hand, a severely critical examination of the results of experiments, and the arrangement of the accepted experiments in the order that shall lead logically, step by step, to a correct solution. Medicine is itself an experimental pursuit. Its higher walks are open only to those skilled in research. The scientific method cannot be acquired by the study of anatomy and pathology in the purely descriptive form in which they ordinarily are presented to the medical student; in this form they are stuff for visual and aural memory—not for the exercise of reason. Nor can the experimental state of mind be readily acquired by the study of clinical medicine. Reliance must be placed on a well-developed highly rational science cultivated to train rather than inform the mind, pursued not for its stores of information but for the highest product of human faculty—the system of inquiry that leads to light through darkness. Too often in our medical schools information is mistaken for knowledge. Only knowledge is power. The getting of mere information wastes the student's time. The vast accumulations of centuries of medical study confuse the undisciplined mind and crush the spirit. The burden of fact which any man can bear is relatively small and each year grows relatively smaller. To find new truths and to look undismayed upon the old is the perfect fruit of education. This physiology can give, and on this power to train should rest the high position of physiology in schools of medicine.

I purpose in this article on the teaching of physiology to show how great is the gap between sound theory and existing practice, to point out the ease with which large classes of students may be carried along the well-known roads that lead to scientific power, and to give the results of one year's experience with a method of instruction different from those heretofore employed.¹

¹ In December, 1898, I laid before a committee of the Faculty of the Harvard Medical School a report on the teaching of physiology. This report was after-

The physiological lectures in medical schools are commonly given by one man and cover the entire field of physiology. This field is much too large to permit of even superficial personal acquaintance by one man. Necessarily, therefore, the instructor must take the chief part of his lecture from textbooks. To this he adds citations of a few experiments or observations taken from the original sources. He has not and cannot have real knowledge as to the present state of special opinion on the majority of the chapters in his subject, because none but a specialist can cope with the constantly rising flood of meritorious research in any one chapter,—to keep pace with the whole of a science which stretches ample arms over the larger part of human and comparative biology is impossible. Physiology could not be taught by the lectures now so largely given, even were lecturers gifted with superhuman knowledge. Physiology deals with phenomena, not with words. Many of these phenomena, for example the heart-sounds, cannot be described; others can be pictured dimly, but only to those who know related phenomena from having actually seen or otherwise sensed them; in no case can lectures properly instruct unless the fundamental facts or closely related facts have first been learned by actual observation in the laboratory. The student should come to the lecture already possessed by his own efforts of the phenomena to be discussed. Chapters, such as metabolism, in which the fundamental experiments are unusually difficult or protracted, should be preceded by less difficult though related chapters. If the obstacles to practical work in any field are insurmountable, the protocols of classical experiments in this field, together with a suitable connecting text, should be studied before the lecture. At present the lecturer too often merely offers a list of facts which mean little or nothing because they cannot be associated in the student's mind with phenomena already observed. The lecturer attempts to remind the student of that which the student never knew. The secondary schools have prepared the student to see nothing strange in this. Most men enter the physiological course persuaded that natural science can be acquired chiefly from books, and leave convinced that a deal of talk and a pennyworth of nature will give real knowledge of the action of living tissues.

A natural science cannot be well taught except by those who have themselves made experimental investigations in the special field which they would teach. No one in these days can work profitably in many fields, and only necessity should make one man attempt to teach them all. A man trained, for example, in the physiology of digestion is likely to have but a relatively feeble grasp on the physiology of the circulation, the nervous system, or the special senses. It follows that most of the instruction in the one-man system does not adequately represent the present state of knowledge. It is behind the times in all except the special field cultivated by the instructor himself. So far as possible, the didactic instruction in each field should be given by the member of the physiological staff actively at work therein, but this wise principle of the division of labor is not usually regarded.

Passing now to the demonstrations, we find that in the larger schools they are made before an audience of

wards presented in part as an address before the Society of American Naturalists (*Science*, January 20, 1899, p. 87). It was printed by the *Boston Medical and Surgical Journal*, December 29, 1898, p. 647, and by the University Press, Cambridge, as a pamphlet, in January, 1900. The proposals there made were accepted by the Harvard Faculty, April 1, 1900, and have been in force during the collegiate year just closed, 1899-1900. Portions of this report, in a more or less altered form, have been included in the present article which is essentially an account of the instruction to be given during 1900-1901.

at least 200. Thus the greater number cannot see the demonstration clearly. If the class be divided into small sections, the brief glimpse allowed each man does not suffice for a full grasp of the details. Very commonly the demonstrations requiring much time are given in a course separate from the lectures. In short, most of the demonstrations as now given are an aid to the memory rather than a means of training in science. The position awarded them by the usual lecturer and by almost every student is one of the evidences of the fundamental pedagogical error which renders most medical teaching of anatomy and physiology so largely futile, namely, the deplorable notion that demonstrations are merely illustrative, and the book and the lecture the main force. Never was the pedagogical cart more squarely before the horse. Contact with nature is the essential of all training in biology.

The laboratory work in large schools is usually done in relatively small sections, and is not coordinated with the regular lecture course. The student feels that the experiments are purely secondary. The experiments are imperfectly arranged into groups. They merely illustrate the textbook. In no case do they present a full picture of any field. The time allowed is so short that criticism of results and insistence upon the proper standard of excellence is not attempted.

The instruction is the same to every student without regard to what his life is to be. Much time is given to matters which have a very remote connection with the future of most students, and which are not better material for training the mind than matter bearing directly on the student's future work.

It is important to inquire how this extraordinary system was developed. The reply is that the present method is a survival of medieval methods; the student of tradition finds a rich field in the history of medical teaching. The teaching of physiology has broken away from anatomy; men now living have taught both subjects in the same course of lectures. Descriptive anatomy became the most conspicuous discipline in medicine at a time when the best mental training could be had only from books, from lectures, from abstractions. It was the flowering time of metaphysics, of authority, of the deductive method. The true principle of approaching nature discovered by the Greeks survived only in a few men of genius, a spark that in our own time has been fanned into flame. Joined to the powerful example of the most liberal education of that period was the difficulty of obtaining material for dissection. Stark necessity united with specious theory to fasten upon this most concrete of sciences the methods of the schoolmen, and to this day the bulk of the instruction in anatomy remains didactic and consists of books, diagrams, and more or less misleading models. Dissections are made to illustrate the book. The printed description is learned by rote, and the dissection practised too often simply as a manual exercise. The anatomy of the medical college is largely a memory drill—such as belongs pedagogically in the secondary schools. These seventeenth-century notions have been passed from anatomy to physiology. That which began as a makeshift has become a dogma.

Practical work in physiology has also been kept back by the erroneous ideas that the cost of apparatus and other materials is prohibitory, that medical students cannot master the details of exact experimentation, that delicate apparatus cannot be trusted in their hands, and that instruction to the extent required cannot be

given to large classes because the course will become too complicated to be carried out.

Perhaps the chief obstacle which has kept physiology in an ancient and now almost abandoned path, is the public belief that because anatomy and physiology were once taught chiefly from books, they should still be so taught; that the functions of living organs can be learned from books with the occasional exhibition of dead organs; that the natural sciences should continue to be studied in secondary schools without laboratory work; in brief, that nature can be studied apart from nature. The public has a just contempt for men who profess to have learned disease without practical observation of the sick,—experience is conceded to be necessary here,—but the public is ready to applaud, and even to compel by law the study of the same organs in their normal state by reading or hearing a description at second hand of what some third person saw. The real drags upon progress are the failure of the secondary schools to teach science by scientific methods, and the fatal conservatism that binds teachers of medicine to a past that we should do well to forget. These venerable delusions no longer impede experts in pedagogy, but unfortunately medical teachers for the most part are more zealous than learned in pedagogy. They fail to see that medical training should be "for power" and only secondarily for information.

If it be replied to these strictures that a system which produces so many able physicians cannot be much in need of improvement, I answer that the men of talent veil the defects of the mass. They owe much to themselves; genius will thrive on the intellectual diet that stunts the merely industrious man. The average student does not build upon a sound foundation. He knows little anatomy, less physiology, and still less chemistry, and even his training in practical medicine has to be supplemented where possible by postgraduate work in a hospital. On the whole, it may be said that his industry has been largely misdirected.

The picture I have drawn of the instruction in physiology in the average medical school will be accepted by teachers of that science. The sense that the usual methods of instruction neither develop nor much inform the mind is general. Careful inquiry should therefore be made to determine how far the defects can be remedied with the means at our disposal. The problem is: How far can the correct theory be realized in practice? To what extent can all students of physiology be taught in the manner in which men are trained to be professional physiologists? Evidently physiologists are likely to study their own subject in the most profitable and labor-saving way.

The expansion of physiology has broken it into specialties. Even professional physiologists can no longer have personal acquaintance with the whole subject, or even a relatively large part of it. To a considerable degree the physiologist himself must acquire his information from reading the work of others. It would therefore be idle to expect the student to get a personal experimental knowledge of the whole subject. His limited time must be used chiefly for training and not chiefly for the acquisition of facts, as at present, and this training must follow the lines laid down by physiologists for their own development.

Deal so far as possible with the phenomena themselves and not with the descriptions of them. Where the fundamental experiments cannot all be performed, fill the gap with the original protocols from the classical

sources. Associate facts which the student can observe for himself with those which he cannot observe. Use as the basis of professional instruction, where practicable, the facts and methods to be used by the student in earning his living. Teach the elements by practical work. Let the student state his observations and results in a laboratory note-book, which, together with the graphic records of his experiments, shall form one of the requirements for the Degree. Control his progress and remove his difficulties by a daily written examination and a daily conference, in which the instructor shall discuss the observations made by the student and supplement them from his own reading. Stimulate the student by personal intercourse in the laboratory, by glimpses of the researches in progress, and by constant reference to the original sources. Diminish the distance between professor and pupil; both are students and both should be fed on the same intellectual diet. There is but one way to get and keep an education. Demand of every student a written discussion of some very limited thesis, giving the results of the original investigators, together with any observations the student has made for himself. Give the more capable students opportunity for original experimental work. Towards the end of the instruction, when the student is ripe for such work, offer a liberal number of courses of didactic lectures with demonstrations. Let each course consist of from one to four lectures not more than 45 minutes in length, presenting all that is known of the chosen subject. These lectures should show the student the historical development of scientific problems, the nature of scientific evidence, and the canons of criticism that help to sift the wheat from the chaff of controversy. From the beginning to the end of the instruction hold fast to concentration, sequence, and election. Such are the lines along which sound theory would direct the teaching of physiology in medical schools.

Concentration, sequence, and election are the safeguards of economical labor.

Whether the student's time is to be given wholly or only in part to the subject taught is the first problem to be solved in planning the actual instruction. Men in training for professional physiology commonly concentrate their energies for a sufficient period on this one subject; and this is regarded as the most economical way of mastering any science, for the ground gained by one day's work is still fresh in the mind when the next day's work begins, and continuity of thought is not disturbed. The plea that the instruction in one subject should be broken by the study of other subjects in order that the instruction in each may have "time to sink in" need not be entertained; experience shows that much of it sinks in so far that it cannot be recovered without the loss of valuable energy. A more serious objection is that the method of continuous application is highly fruitful in men of exceptional powers, who are keen in spite of protracted effort, but is wasteful for the average brain, which is fatigued and unresponsive after some hours of unremitting labor. The truth of this must be allowed; but the objection does not apply to wide-ranging sciences such as anatomy and physiology, which are not narrow, hedged-in areas, but which consist rather of broad and diversified domains composed of many contiguous fields, the varied nature of which is a perpetual refreshment.

A correct sequence of study is also highly important. Very often in medical schools the lectures in physiology

are given before the student has any acquaintance with the anatomy of the structures considered, and still more are heard before the student has any true anatomical knowledge,—that based on actual contact with tissues and not upon a glimpse of a distant prosection or a hasty glance at a diagram. Similar instances are not uncommon in later parts of the curriculum. The natural sequence demands that the study of structure should precede the study of function, and the study of the normal precede that of the abnormal. Thus the natural order of medical study is descriptive anatomy, physiology, pathology, and medicine. There is a considerable advantage in treating organs individually, studying their structure, physiology, pathology, diseases, and treatment in continuity, but practical difficulties in arranging such a course make this inadvisable.

Election is correct in theory and unavoidable in practice. Generations have passed since it was possible to teach every clever student all things. Yet in many schools the effort is still made. The herd of students is driven hastily past the monuments of genius and learning in the hope that they who run may read. Students are exhorted to be great, while littleness is thrust upon them. The obstetrician and the ophthalmologist still receive the same instruction. It is obvious, however, that this indiscriminate gorge will be soon an unpleasant memory. The wonderful growth of medicine is breaking bonds already centuries old. All minds in one mould is ceasing to be the ruling axiom in medical teaching, not because it is a terrible delusion which by retarding discovery has cost the lives of countless thousands, but because it is no longer practical. Success demands some acquaintance with all subjects and an intimate knowledge of one. Day by day the walls rise higher between one specialty and another. The parting of the ways begins at the threshold. In anatomy, physiology, and pathology the student should spend his time on those portions which are directly associated with his future work as practitioner or investigator.

This early election will be strenuously resisted by partisans of the tradition. They will contend that the present instruction embracing the entire field is known to give a very inadequate acquaintance with the subjects taught; therefore, instruction covering only a part of the ground will give still less. The argument is beside the mark. The present method of instruction would be inadequate in any event. The medical degree is granted for superficial information in twenty-five or thirty subjects. The sign of the scholar and scientist, namely, thorough knowledge of some one field, is wanting. Yet this training of the scientist is more and more necessary for success. Moreover, a thorough training in at least one subject increases the power of acquiring the fundamental data of related subjects while it protects the mind against superficiality. A further necessity for election is seen in the fact that the great medical schools are university departments. They are attended by an increasing number of men who will never practise medicine but will become investigators in some branch of biological science.

Following the idea of concentration, sequence, and election, I have proposed that the student's undivided attention be given to one principal subject at a time. The principal subjects in medicine are anatomy, physiology, pathology, and clinical medicine including surgery. The four years' course in medicine is divided into eight terms or semesters which usually comprise 16 weeks of instruction. The first of the 8 terms may

be given to the primary course in anatomy, including histology; the second to the primary course in physiology, including physiological chemistry; the third to the primary course in pathology, including bacteriology; the fourth to pharmacology, clinical chemistry, and physical diagnosis; and the four remaining terms to clinical medicine and surgery. The primary courses just mentioned provide the instruction in anatomy, physiology, and pathology which every student is advised to take. Advanced instruction in these subjects may be offered in subsequent elective courses.

To meet the needs of the several classes of students found in universities the department of physiology must provide: 1. The primary course already mentioned, suitable for every student of biological science, including medicine; 2. An advanced course, intermediate between the primary course and research; this advanced course will be taken by candidates for the degree of Doctor of Philosophy who have selected physiology either as their principal subject or as one of the two or three subordinate subjects required of such candidates. 3. Opportunities for physiological research.

The primary course in physiology is held from 9 A.M. to 1 P.M. daily during the second term of four months in the first year of the medical curriculum. The afternoons of these four months are devoted to physiological chemistry. The primary instruction in physiology is divided into three parts. Part I, of 5 weeks' duration, provides thorough experimental work in some limited field. In this, the student should acquire the point of view, the general physiological method, training in technique, and a complete knowledge of one or more tissues to serve as an introduction to the physiology of the remaining tissues. There can be little doubt that the physiology of muscle and nerve should be chosen for this purpose. It is the most fully developed chapter in physiology and is well adapted to train the mind in habits of exact experimentation and close reasoning. Moreover, the physiology of muscle and nerve is in large measure the physiology of all living tissues, so that a man learned in this one field is in effect already acquainted with the general principles of physiology. Part II, of about 7 weeks' duration, comprises carefully arranged fundamental experiments giving in turn the elements of each field in physiology except that of nerve and muscle which has just been studied. In Part III, covering the remainder of the term of 16 weeks, the instruction is divided into special courses on the physiology of the eye, ear, larynx, digestion, the spinal cord, the innervation of the heart, etc. Each course is long enough to include all the practicable experiments that should find a place in a systematic, thorough study of the subject. The number of such experiments, and hence the length of the special courses, is naturally different in the various instances; thus the experimental physiology of the eye occupies more time than the physiology of the larynx. The student may elect the subjects that most interest him, but must choose a sufficient number to occupy him during the entire four weeks of instruction. In planning these courses, the aid of distinguished specialists is sought.

Each student is required to present one written discussion of some small and sufficiently isolated thesis, giving the work of the original investigators. The way of dealing with the sources at first hand is thus learned. Many of these essays are read and discussed before the class. The discussions begin with the sixth week of the course and are held daily during nine weeks. None is

held during the last two weeks. The literature of each subject is divided into two portions and each is assigned to one man. The 54 subjects, therefore, are presented in 108 essays. The men chosen for this purpose are the best in the class; their choice is determined at first by the results of their examinations in anatomy, and, so soon as practicable, by the results of their work in physiology. In addition to the two men who read theses, one or more of the investigations on each subject are studied by four men, who are thus specially qualified for the discussion. The four are selected in turn from the whole class. To illustrate, let us take as an example "The transmission of the cardiac excitation wave." One student defends the theory that the cardiac excitation wave is transmitted through muscular tissue; a second defends transmission through nerve tissue. Each presents a carefully written account of the evidence pro and con. The four men, each of whom has read at least one of the investigations on this subject, lead the discussion, which is held by the entire class and the departmental staff. The subjects chosen for discussion are, as a rule, such as cannot be fully studied in the laboratory. Thus the discussions complement the remaining instruction. The subjects to be discussed are bulletined before the appointed day, so that the class may come to the discussion somewhat prepared.

In the last two weeks of the course, students who have performed their experimental work especially well may elect instruction in physiological research. The subject chosen must necessarily be very narrow, and, where possible, should be one the literature of which has been already examined in the preparation of the student's thesis. Experience has shown that after 14 weeks of strenuous labor in experimental physiology, the student of average ability learns to work rapidly and carefully, so that much can be accomplished in two weeks of experimentation in one small subject. Even a very brief experience of investigation is of the greatest value and interest. Examples of subjects suitable for training in investigation are: "The compensatory pause;" "The tetanus curve;" "The action of calcium and sodium ions on rhythmic contractility."

Beginning with the second week of the course, a daily written examination, 20 minutes in length, is held. One or, at most, two questions are asked. They concern the student's own experiments. The purpose of the examination is to cultivate precision in statement. The emphasis which the question gives imparts a correct perspective. Further, the examination reveals men whose indolence or incapacity marks them for special care. The following questions are some of those asked in such examinations: "Give experimental evidence to show where stimulation begins on the closure of the galvanic current? Explain the difference between the stimulating electrodes and the physiological anode and cathode in the stimulation of human nerves? Give the experimental basis for an explanation of the auriculo-ventricular interval?"

The didactic instruction consists of a ten-minute talk in the laboratory, commenting on the examination of the previous day and explaining any special difficulties in the experiments, and of a daily lecture. In every instance this lecture is intended to discuss experiments. Wherever possible the experiments are to be performed by the students themselves before coming to the lecture. Experiments which the students cannot do for themselves are studied by them from the original protocols, furnished with a suitable explanatory text. Thus the

fundamental elementary information is gained from the original sources before the lectures. The students are questioned concerning these fundamental experiments. The questions are arranged in the sequence required for a systematic presentation of the subject. Wherever necessary, the lecturer adds from his own stores to the information already possessed by the student. The class is encouraged to question the lecturer concerning matters not quite clear. At the close of the exercise the lecturer sums up briefly. The end in view is the development of the mind rather than the imparting of information. For example, the fact that the pressure of the saliva in the ducts of the submaxillary gland during secretion is higher than that of the blood in the carotid artery is not presented as a fact to be memorized, but is discussed with reference to its bearing on secretion by filtration; the student has learned the fact itself from the original source before coming to the lecture. Some of the lectures on special subjects, such as the eye, are given by distinguished specialists in practical medicine. Each instructor gives as an elective one or more lectures describing, with demonstrations, his own investigations; the investigator discussing his own experiments is a powerful intellectual stimulus; too little account has been taken of this educational force.

The student should be provided with what may be called a laboratory textbook. This textbook consists of a series of experiments and observations, taken from the original sources, and arranged in the sequence suited to develop the subject. Very often the historical sequence serves this purpose best. The description of the experiment follows the original so far as practicable. The experiments are provided with a suitable commentary text. The student is made to feel at every step that physiology is an experimental science, that the only material proper for discussion consists of observations and experiments free from error, and that safety demands constant reference to the original source. The laboratory textbook is supplemented by the student's laboratory notebook, in which the student preserves the graphic records of his experiments and the notes of his observations.

The examinations held in the primary course consist of: 1. The daily written examinations, 75 in all; these are corrected daily and the papers of each student filed by themselves. 2. A written examination which is held at the end of the course and includes all that is taught. 3. The laboratory notebooks; these are collected and marked once a week. 4. A practical examination. This practical examination so well illustrates the character of the work accomplished under the method of instruction described in this article that an extract from one of the examination papers may be of service.

DEPARTMENT OF PHYSIOLOGY.

Practical Examination, May 28, 1900.

NOTICE.

Each student is assigned the number written on the tag fastened to his locker. He is required to make either one of the two experiments bearing his number and to write an account of his results on the blank furnished herewith. Where the results of the experiment are not expressed in a graphic record, they must be demonstrated to an instructor, who will then countersign the student's account of the experiment.

Questions.

- I. A. Show the effect of inhibition of the heart on arterial blood-pressure in the frog.
B. Show the influence of temperature on the form of the contraction wave.
- II. A. Prove that the spinal cord possesses vasomotor functions.
B. Measure the electromotive force of the demarcation current (current of injury) of nerve or muscle.
- III. A. Furnish evidence that the ventricular contraction wave may be transmitted by muscular tissue.
B. Demonstrate polar stimulation by the galvanic current.
- IV. A. Show that the fields of distribution of sensory nerves overlap.
B. Show the influence of an increase in peripheral resistance on the blood-pressure in the frog.
- V. A. Demonstrate the function of the anterior roots of spinal nerves.
B. Prove that the extensibility of muscle is increased in tetanus.

The final written examination counts 50, the daily themes 30, the practical examination 15, and the laboratory note-book 5, in a scale of 100.

After this brief yet comprehensive glance at the instruction, let us consider the question of ways and means. Let us suppose that the number of students in physiology is 200. Experience shows that it is of advantage to have the men work in pairs; indeed, many of the experiments in physiology cannot be done by one man alone, because the necessary manipulations require an additional pair of hands. Thus 100 sets of each apparatus must be provided for Parts I and II of the above course, in which the students all do the same work at the same time. In the elective subjects the number of sets is less, first, because the number of students in any one subject is smaller, and, secondly, because the character of the work permits a method of rotation to be applied. Expensive apparatus can be provided in sets of four or more, and the section divided in such a way that while four pairs of men work with one set others can work with the other sets, and so on. Much of the apparatus for the special courses is that in use by physicians in everyday practice, and may be obtained in small quantities from the manufacturers for little or nothing, as the advertisement of their product by its selection to serve as a model in the university is a valuable consideration. The cost of the remaining apparatus for students should be covered by \$50 for each pair of students, or \$5,000 for 200 students. Much of this apparatus is permanent, some will last for 20 years or more without renewal, and some is likely to require frequent renewal. If it be assumed that the whole plant must be replaced every 10 years—surely a liberal estimate—the entire cost of apparatus, including simple interest at 4% on the original investment of \$5,000, would be met by setting aside \$3 a year from the fees of each student—a sum within the reach of any large medical school. It is assumed that one piece of each kind of apparatus shall be made by the laboratory mechanic, and bids for a hundred duplicates taken in the open market.

The staff of the physiological department, including physiological chemistry, should consist of two professors, three able instructors, eight assistants, a mechanic, a

secretary, three laboratory boys, and a scrub-woman. All these should give their entire time. The cost of such a department is about \$22,000 per year. A suitable building containing separate laboratories of physiology and physiological chemistry, for 200 students, suitable rooms for research, an ample library, a machine shop, with accommodation for the necessary animals, etc., costs \$150,000.

Little need be said concerning the instruction intermediate between the primary course and research. In the intermediate course the experiments chosen for the individual student vary with his goal, and are arranged in the order that seems best adapted to train the mind for research in the direction desired.

The methods of primary and advanced instruction here presented are obviously the methods of the investigator. They can be carried out effectively only by those whose chief purpose is the advancement of human welfare by discovery. In many schools, instructors are still selected mainly because they can talk agreeably of the work of others; in some, the instructor must have made one experimental study in the subject which he teaches; in a very few of the large schools, the higher positions are occasionally bestowed on men to whom research is more than a memory, but these positions almost invariably are burdened with a great mass of petty administrative detail. The university devotes these men to researches which the university prevents them from making. Thereby its best minds are set to its lowest work. A change is necessary here. No man who has not made at least one experimental investigation should be appointed assistant in a department of physiology, no man who has not shown marked capacity for original work should be made instructor, and the professor's chair should be filled only by those in whom the ardor of discovery is not likely to be cooled by the advancing years. At least half the day should be set aside for research, and the hours thus reserved for the highest studies should be guarded against every encroachment. The best elementary instruction can be given only in the atmosphere of research. Discovery fires the imagination of youth, consoles the aged, and lifts the mind from mediocrity to greatness.

ON THE TEACHING OF PHARMACOLOGY, MATERIA MEDICA, AND THERAPEUTICS IN OUR MEDICAL SCHOOLS.

By JOHN J. ABEL, M.D.,

Professor of Pharmacology in the Johns Hopkins University.

It would seem unnecessary to define in the columns of a medical journal what is meant by pharmacology, but the frequent confusion of this term with pharmacy by those who are not teachers of medicine must serve as a reason for a brief statement of the methods and aims of this branch of medical science. The vague and often erroneous use of the word pharmacology seen in earlier writings, as in the definition of Nathan Bailey (1736), "a treatise concerning drugs," or in that of Samuel Johnson (1755), "an equivalent of pharmacy or pharmaceutics," is still frequently met with in our own time. Briefly stated, pharmacology tries to discover and explain all of the more obvious functional, and the less noticeable chemical and physical changes that occur in a living thing that has absorbed a substance capable of producing such changes, and it is also its province to learn the fate of the substance thus incor-

porated. It is not, therefore, an applied science like therapeutics; it is one of the biological sciences, using that term in its widest sense.

The interested student of the history of medicine discovers in every epoch some man far in advance of his contemporaries who may be looked upon as a leader in one phase or another of our subject. Such were Erasistratus, Dioscorides, Mesua, Avenzoar, Paracelsus, and Haller; and when we turn our attention to the modern laboratory methods of pharmacology and the lasting achievements gained by their aid, we find that the first great impulse was given by Magendie. That great experimenter's classical research on the physiological action of opas, undertaken early in the present century, was the first instance of the completely successful application of the analytic method in the study of the coarser changes of function which follow on the use of drugs. As early as 1813 he had also proved that the blood is capable of taking up and carrying metallic poisons, but it was not until the middle of the century that the pernicious doctrine of the "action of poisons by sympathy" received its death-blow. About the middle of the century, too, the memorable experiments of Claude Bernard and of Kölliker proving that the paralyzing action of curare centers in the end plates of the motor nerves gave further evidence of the value of physiological analysis as applied to the study of drugs.

Brilliant discoveries of a similar character have followed from time to time, and we have now innumerable instances of the rational analysis and at least partial comprehension of the more obvious functional changes that follow upon the administration of drugs and poisons. One has but to recall atropin, pilocarpin, muscarin, eserine, cocaine, digitalis, amyl nitrite, chloral, chloroform, ether, salicylic acid, ergot, and other well-known drugs and poisons, to appreciate how great is the store of knowledge relating to the action of drugs which is at the disposal of the modern student.

It was experiments like those of Magendie and his successors that induced Mitscherlich (1847), and later Buchheim, to insist on the insufficiency of the mere bedside study of the action of drugs and led to the erection of special laboratories in which experimenters can build up their science undisturbed by the intrusive demands of practical utility. Buchheim's pharmacological laboratory, founded at the University of Dorpat in 1849, was the first public institution of the kind in the world and was long the best equipped in Germany. But it was not alone in Germany that attention was called to the new methods. The medical literature of our own country contains some eloquent pleas in favor of the analyses of medical problems by means of experiments. From among these I would call attention to that of Dr. R. Cresson Stiles, contained in a worthy but little-known research, published in 1865, entitled: *On the Direct Influence of Medicinal and Morbific Agents upon the Muscular Tissues of the Bloodvessels*. This physician was interested in the problem as to how the blood, in febrile conditions, acts upon the circulatory mechanism. He evinced considerable experimental skill, as shown by his use of the "surviving" umbilical artery in his transfusion experiments, and he seems to have had some premonitions of our later theories, for he subjected the umbilical artery to the action of blood drawn from a patient with typhoid fever and compared the results thus obtained with those noted when normal blood was used.

In one part of his paper he defends and justifies his methods in the following words: "Moreover, it is not to mere clinical experience that we must look for a revelation of the laws of disease. The laws of chemistry were not discovered in blazing fires or crumbling rocks; the laws of hydrostatics and hydraulics were not revealed in torrents, tides, or ocean currents, nor those of pneumatics and electricity in winds, whirlwinds, and thunderstorms; much less could it be rationally expected that the laws of pathology should be discovered amid the much greater complexity and more multitudinous conflicts of elements presented to the physician at the bedside of a diseased or dying patient. It is in the laboratory, and by artificially contrived experiments that the clue has ever been spun and the torch lighted to guide through the labyrinths which hide the arcana of nature."

By means of "artificially contrived experiments" we are today enabled to demonstrate in detail how drugs act on the various organs of the body and what is their immediate, specific action on the parts of a compound mechanism like the circulatory apparatus. Thus we teach the student of our day the method by which is analyzed the action of a drug on the heart and arteries, on the vasomotor, cardioinhibitory and respiratory centers, on the terminals of the vagus, on the spinal cord and brain, on the intestines, the uterus, the salivary and other glands, the iris, ciliary body, etc. Conceptions familiar to the therapeutician are thus resolved into their elements and made accessible to the beginner.

The empiricist may perhaps assert that an experimental demonstration and analysis of the manner in which atropin, for example, causes dilation of the pupil is of little service to him, that the clinical fact is all-sufficient. A physician of this practical turn of mind may long use with safety his corrosive sublimate, his ether, his salicylic acid, his homatropin, eserine, and other drugs; but, sooner or later, if he is an observing man, he will find himself confronted by doubtful and obscure questions which directly concern the welfare of his patient, questions that can only be cleared up with the help of the "artificially contrived experiment." No branch of practical medicine can afford to neglect the study of the principles and methods of pharmacology. For, like other branches of experimental science, it teaches conservatism by pointing out how vastly complex are the phenomena of the action of drugs and showing how little is clearly understood aside from the grosser and visible changes which follow upon their administration. The dogmatic use, in symptomatic treatment, of cardiac stimulants, depressants, antipyretics, and innumerable other remedies whose extraordinary virtues are lauded in commercial circulars, finds no justification in the teachings of pharmacology. Its teachings are not always or immediately convertible into bedside dogmas.

It must be confessed that the therapeutic nihilist who uses only what is indispensable among drugs, but who is wise in the curative power of air, water, food, rest, and exercise, will have less to answer for in the final reckoning than his drug-enslaved colleague who prates of controlling disease in its every symptom with this or that panacea and who is guilty of the premature application to practice of what are only unproved theories.

Pharmacology gives no support to the unthinking worship of canonical authority. In instances when true specifics and well-founded remedies are manifestly powerless, the plan outlined by John Locke is as ap-

plicable now as it was when he wrote: "You cannot imagine how far a little observation carefully made by a man not tied up to the four humours, or sal sulphur and mercury, or to acid and alkali, which has of late prevailed, will carry a man in the curing of diseases though very stubborn and dangerous; and that with very little and common things, and almost no medicine at all."

In an age in which pathology and diagnosis are so far advanced and in which more genuine help is derived from the rational use of drugs than ever before in the history of medicine, haphazard drugging is unpardonable, and still more to be condemned is a fanatical and conceited adherence to dogmas based on a superficial understanding of complex physiological principles.

I have spoken thus far only of the older and well-tried methods of pharmacology, methods that are still fruitful, although newer tendencies are now followed and fresher fields are being tilled. The more detailed examination by means of modern physiological methods of the respiratory, circulatory, muscular, nervous, and other functional derangements which are met in "intoxications" will surely lead to most important results. One of my younger colleagues, who is now carefully reviewing the list of drugs that act on the heart, tells me that not a single one of them has been studied on all sides from a modern physiological standpoint. Digitalis alone of the list has been the object of a fairly complete physiological examination, but everywhere in this field of the *cardiaca* there seems to be a great accumulation of physiological facts ready for the coordinating hand of the pharmacologist. As elsewhere, judgment and special knowledge are required, and the day has long passed when he who knows the drugs of the pharmacopeia and their clinical uses and who is able only to set up a kymograph and attach a few registering instruments can claim to be a pharmacologist. Such an one will not travel far beyond the region of mere routine, a region chiefly of pedagogical interest.

Thoughtful pharmacologists have also made it the object of their investigations to understand more fully the chemical and chemico-molecular phenomena that underlie and accompany the coarser changes to which reference has already been made. The principles of physics and chemistry must furnish the pharmacologist with provisional or permanent explanations of these phenomena. Like the physicist, he is well aware, however, of the "futility of attempting an ultimate explanation of natural phenomena," and fully recognizes the limitations of his method. At present we make use of a hundred terms which convey anything but a clear idea to the mind. Take so old a drug as ethyl alcohol, for example, and endeavor to explain why it is not a dynamogenic substance for muscle-tissue. We hide behind such expressions as "protoplasm poison" and the like. We know that alcohol is oxidized in the tissues and that liberation of energy follows, but a more careful study of the subject shows that oxidizability and the liberation of energy are not alone the measure of dynamogenic value. A closer study of the intermediate steps in the oxidation and of the chemico-molecular processes which are initiated by these products and by the alcohol itself will alone clear up a problem of this sort.

Knowledge of the "chemical architecture" and constitution of a given drug often enables the pharmacologist to trace it in its passage through the body, and in

studying its chemical fate and final disposition, valuable facts bearing on the synthetic, oxidative, reductive, or splitting powers of various tissues and organs have been brought to light. In this way, too, intermediate products of metabolism are discovered and glimpses of hidden chemical processes are obtained which throw light on deep problems of pathology and clinical medicine. The results of the study of the relation of chemical constitution to physiological action as yet apply only to certain families of chemicals. They have not led to any principles of universal application. Recently a clearer statement of the action of whole series of drugs and poisons has been given in the language of physical chemistry. Thus, this or that feature of the pharmacologic action of many acids is in proportion to the concentration of their hydrogen ions and depends to a lesser degree on the specific properties of their anions. The toxic or disinfecting action of a series of dilute metal hydroxids stands in relation to the concentration of the OH ions. The theory of electrolytic dissociation, on the other hand, plays but a subordinate part in determining the toxic properties of phenylic and other compounds. But wherever this theory is applicable to the problems of our science, it has put them in a new light. Yet it must be remembered that when we say that pharmacologic action in a given case is *ionic*, we are still far from the last possible analysis and explanation of the observed phenomena.

A new epoch began with the belief that many diseases are but instances of acute or chronic intoxication. The growth of the doctrine of toxins forced upon us by modern experimentation in bacteriology is seen in pharmacological literature and methods. The recent studies in the action of toxins and antitoxins, on the nature of immunity, on the nature and cause of diabetic coma, uremic poisoning, and other pathologic conditions in which poisons generated within the body play a role, are all instances of researches in which repeated use of pharmacologic methods and principles is made. It is evident, then, that pharmacology deals with the most fundamental conceptions of medicine, that it conserves and augments a variety of facts, methods and principles which are of service not alone to every branch of the medical art, but also to other branches whose subject-matter confines them to the laboratory, the private study, and the lecture hall.

When and how shall this subject be taught in our medical schools?

First, as to the time when it should be taught. I hold that this should be when the student begins his clinical studies and not before. I do not deny that it is often difficult to make room for this subject in the first clinical year, but the argument which in reality excludes it is that pharmacology, like physiology, is so capable of illustration by laboratory experiments and of presentation in the form of lectures, that it can be taught as soon as the student has the needful foundation in the way of physiologic chemistry, anatomy and physiology.

But this argument ignores the fact that every drug has its clinical uses, that the teacher of pharmacology is expected to point out what these uses are, and that it is impossible to avoid reference to diseases and their symptoms. In the interest of the student, by way of lightening his work and making it more profitable to him, it is imperative to teach pharmacology hand in hand with the early clinical work. For now he begins

to see drugs used; he notes, for example, how a patient behaves under ether; for what conditions the clinician prescribes iron, quinin, mercury, salicylic acid, codein, digitalis, potassium iodid, amyl nitrite and the like; what antiseptics and local anesthetics are used by the surgeon. He perhaps sees an outpatient with a gangrenous finger due to his having swathed it in 5% carbolic acid; he learns of mercurial stomatitis, of palsies and neuritic affections and anemias caused by the heavy metals, of exanthems due to drugs; he sees examples of iodism, cinchonism, etc., and specimens of urine that show misleading features in consequence of certain drugs. Though only a beginner, he meets at every turn with some practical application of the articles of our materia medica. Drugs now have some significance for him, an interest is aroused in their action, important data and conceptions are gathered by actual experience.

It must be remembered, too, that a description of the symptoms that appear when more than the therapeutic dose of a drug is given is an integral part of the teaching of the pharmacologist. In a word, toxicology is inseparable from pharmacology, and instruction in this branch, so far as it is not of a chemical or medicolegal character, deals with clinical and pathological data. How wasteful of energy is it to teach this part of the subject at a time when all practical knowledge of such data, with the exception of that gained by experiments on animals, is lacking! What does the student profit from descriptions, for example, of the nature of cocain, atropin, opium, or arsenical poisoning, at a time when he has seen nothing whatever of bedside medicine?

To say that the practical examples of the uses of drugs and of their toxic action can be as well learned by the student after he has taken the course in pharmacology is to deny the principle of economy in intellectual work, and indicates a lack of appreciation of the fact that the applied and the theoretical parts of pharmacology are not capable of a sharp separation in courses intended for medical students.

The question as to *how* we shall teach pharmacology may now be considered. But first, a few words concerning instruction in *toxicology*. It has already been stated that, from a scientific point of view, no sharp line of demarcation can be drawn between this subject and pharmacology. Only when the medicolegal, the industrial, or the chemical sides of toxicology are considered is it advisable to make a distinction. But these aspects of toxicology should not be neglected in our medical schools. Even in institutions in which the general principles and methods of toxicological analysis are taught in connection with the work in chemistry, or in which extensive courses in legal medicine and in hygiene are given, there will still be left a large field to be covered by the pharmacologist. In my own experience I have found it advantageous to give a brief course in toxicology as a preliminary to the work in pharmacology. My students begin their work with me at the conclusion of the first third of their second year, at a time, therefore, when they have had no clinical work and but little pathology. The course requires eight weeks, and there are two afternoon sessions and a Saturday morning recitation or conference. The points aimed at in the course are: First, the acquisition and comprehension of the physiological phenomena of intoxications; second, certain important phases of the subject regarded as a part of forensic medicine; third, the more important chronic intoxications which are

met with in the arts and industries; and fourth, the general principles of toxicological analysis as illustrated by actual practice at the laboratory desk.

Nothing in the way of vivisection is done by the student himself in this course.

The afternoon's work begins with a brief lecture and with demonstrations of a physiological character. In these a number of circumstances bearing on the action of a given substance, whether used as a poison or as a drug, are clearly set forth. These demonstrations constitute the best introduction to pharmacology. Some of the points illustrated are the varied symptoms of poisoning, such, for example, as the paralysis of the respiratory center by hydrocyanic acid or morphin; the influence of the place of application, as illustrated by the fact that not all mucous surfaces absorb poisons with equal rapidity; the rapidity of dispersion of poisons throughout the body; the paths of elimination for drugs and poisons, and the storage of drugs in various tissues and organs, and the great differences that obtain in these two fields; changes in the blood; the anatomical lesions produced by powerful poisons, such as arsenic, phosphorus, nitric acid, carbolic acid, alkalis, etc. A wide range of demonstrations, in which organisms ranging from paramecia to dogs and rabbits may be employed, is at the disposal of the instructor, who has access to original literature. In this way the beginner receives ocular proof of the fact that an intoxication, whether acute or chronic, is as complex a matter as any of the clinical conditions that he will later study in the hospital; that drugs can produce fever, convulsions, paralysis, and other symptoms; lesions of the various organs, alterations of the secretions and of the blood—in short, an interest in the manifold problems of medicine can here be aroused. It is, of course, understood that the rules of the physiological laboratory in regard to anesthesia are to be observed in work of the above character. During the first week of this course the demonstrations extend so far into the afternoon that the student has no time left for laboratory work, and can only arrange his desk for the chemical work.

The chemical work of the student is so planned that it shall instruct him in certain methods which will be of use to him in his later work in clinical medicine and will enable him also to make at least the necessary preliminary tests in a case of suspected poisoning. A small laboratory manual drawn up by the instructor is placed in his hands and its directions are modified from year to year. The ground covered in the laboratory includes the methods of isolating volatile poisons and the analytical methods applicable to the detection of small quantities of this class of poisons; the search for alkaloids and glucosids by the methods of Dragendorff, Brouardel, Kippenberger, and others, some typical poisons of these classes being mixed with foods and subjected by the student to processes suitable to their extraction; the search for metallic poisons and non-volatile acids; a study of blood-stains and the separation of blood from rust-spots, etc.; a spectroscopic and simple chemical study of the various hemoglobin derivatives as methemoglobin, hematin, reduced hematin, hematomorphin, carbon monoxid hemoglobin, etc.; a study of the changes in the urine induced by drugs.

In a course of this kind a wise selection of examples must be made and assistance must be given to the student by means of class demonstrations and informal talks, as well as by instruction at the laboratory desk.

In the past few years our students have come to us

with a better preparation in chemistry, and many of them have already had a special course in the detection of metallic and other poisons.

To avoid repetition we have therefore arranged a few class demonstrations showing the best methods of oxidizing organic matter and of detecting arsenic, antimony, lead, mercury, and phosphorus, paying especial attention to the simpler preliminary tests which shall enable the physician, if need be, to ascertain with certainty whether one or another of these poisons is present. The object of this chemical course is, therefore, mainly to give the student a bird's-eye view of the field, with a certain technic of an elementary sort and to further improve his chemical knowledge, something for which the modern physician finds more and more practical uses. Should the student who has taken such a course ever find himself involved as a medical expert in a medicolegal case he will not be entirely incapable of comprehending the controversial points which are agitating the chemical experts in the trial.

Along with this chemical work goes the reading of selected chapters of a good textbook, recitations, and informal talks by the instructor on special subjects, as the commoner poisonous plants of the country, or the intoxications met in the modern arts and industries. The talk or the recitation, as the case may be, is held early in the afternoon, before the laboratory work is begun. An hour on one other day on which no laboratory work is done is also given up to a recitation on assigned subjects.

It will be seen that there is little in the way of didactic lectures. The student profits most when, for example, he has himself detected opium in some mixture and has read his Blyth, Kobert or Lewin and then meets his instructor, to discuss with him, in an informal manner, the chief points in the physiologic action of the poison in its chronic use, or in its medicolegal significance and chemical detection. His previous reading has aroused his interest, and taken in connection with his chemical experiments and the demonstration on the living animal, it has prepared him for a conference whose chief aim is to help him to separate the essentials from the nonessentials.

The remainder of the year is devoted to *pharmacology*. This course is only in part a laboratory course, the class working in sections of four. Even if it is impossible for the student to perform more than a half-dozen experiments, this kind of work is too valuable to be omitted. Nowadays, when simple apparatus can be had at a comparatively low cost, it is not a matter of great difficulty to give every four students out of a class of 75 a number of highly instructive experiments. These may be so arranged that the student himself learns the chief pharmacological facts involved, say, in the action of ether and chloroform, the diuretics and purgatives, atropin, morphin and chloral, or digitalis, the nitrites and other agents that have a pronounced action on the circulatory apparatus.

I would, therefore, urge that at least 5 or 6 topics be made the subject of laboratory experiments to be performed by the students themselves under competent direction. The "artificially contrived experiment" has made the subject what it is; it is that instrument of knowledge with which the teacher and investigator tests the theories of the day; it is his very shortest road to certainty of opinion. Why, then, should it not give a clearer insight to the student also? As Porter so tersely puts it, "the meat on

which professors are nourished is just the diet for students."

As for the rest of the experimental work, numerous class demonstrations are necessary. The work in physiology, perhaps going on at the same time, has prepared the student to grasp the principles to be illustrated by the more complicated experiments and perhaps also made it unnecessary for the student himself to perform the many simple experiments to which he is equal, but which can be more quickly performed for him. For we must keep in mind that as Professor Welch has said, "Laboratory methods are extremely time-taking and are not adapted to teach the whole contents of any of the medical sciences." I need not recount the list of practicable class demonstrations. There is hardly a drug of importance for which a good demonstration is not to be found in the various scientific journals. We know that the list of drugs in actual use is very large, but if we ask what are those that have been found to be really indispensable to the surgeon, the gynecologist and obstetrician, the internist, the ophthalmologist, dermatologist and other specialists, we can easily reduce our portentous list to some fifty instances. Let these constitute the basis of instruction and serve as types; take these up in great detail, and whenever possible connect with them less important ones of similar action.

But to assist the student to master the contents of his particular subject should not be the only aim of the medical teacher; he should seek to arouse an appetite for all that is fundamental in the science of medicine; he should stimulate to inquiry, to a searching and logical analysis of the phenomena to be grappled with, be it in the laboratory or at the bedside. And in striving to carry out this high purpose, his own life work, his spoken words and his attitude toward his pupils are his chief means of influence.

I have thus far said nothing on the subject of *Materia Medica*. I do not believe that special instruction in this branch is called for. In the day when the student to the medical school entered with little knowledge of chemistry, botany, and other sciences, it may have been well enough to give special courses on the physical, chemical, and botanical characteristics of drugs, but the result in general was to overburden the student's mind with a multitude of dry details of interest or value solely to the pharmacist or to the student of pharmacognosy. When I began to teach pharmacology ten years ago, I discarded all separate instruction in *materia medica*. My plan has been to give only those points which are of actual importance to the student of medicine or which he ought to know for historical reasons. The drugs and preparations which are discussed in lectures and recitations are placed on a table where all may examine them, and the more important ones are passed from hand to hand while they are being described. In speaking, for example, of rhubarb, digitalis, cinchona, ergot, or opium, only brief historical remarks, with short accounts of their chemical composition and their behavior towards solvents are introduced.

Certainly all unnecessarily detailed description of crude drugs, of their active principles, or of the modern synthetic remedies, is out of place in a medical school. The instructor should allow himself but the briefest introduction as to the physical and chemical properties of a drug before he begins the more important discussion of its pharmacological action. Thus,

when chloral is the subject, he will describe its chemical relationship to the other anesthetics and hypnotics, its solubilities, its deliquescence, its decomposability by alkalis, etc. A rapidly-performed test-tube experiment showing how chloroform is split off when it is brought into contact with an alkali will prevent the student from prescribing it in this form. Such a method of treatment consumes but little time and is easily comprehended by the student who has had a suitable preliminary course in chemistry. In a word, I would teach *materia medica* in direct connection with pharmacology, letting it serve in the case of each drug or class of drugs as a brief introduction to the latter and giving only such parts as are indispensable to the physician in his administration of drugs or of such historical significance that they ought not to be neglected from the culture point of view. Here, as everywhere in our crowded courses, wise selection is our only safeguard. With regard to the *pharmacopoeial preparations* it has always been my plan to require only a knowledge of the more important ones, the student being requested merely to read over those of lesser importance. There is much truth in the remark made by William Withering more than a century ago, that "the ingenuity of man has ever been fond of exerting itself to vary the forms and combinations of medicines. Hence we have spirituous, vinous and acetous tinctures; extracts hard and soft, syrups with sugar or honey, etc., but the more we multiply the form of any medicine the longer we shall be in ascertaining the real dose."

Certain chemical and physical points which have a bearing on the combination of drugs as called for in prescriptions, or official preparations may be taken up again in a brief course in *pharmacy*. I cannot believe that the art of preparing drugs for therapeutic use requires a prominent place in the better medical schools of the day. The young physician who is fairly well trained in chemistry can get all that is necessary in the way of pharmacy out of a course of at most a dozen or fifteen lectures in which systems of weights and measures, incompatibles, and special points relating to prescriptions are dealt with, and in which demonstrations are given of how pills, tablets, suppositories, tinctures, and other official preparations are prepared.

In schools where the student is admitted with but a poor elementary training much more than this may be necessary. But, even under the most favorable conditions the limited course above outlined will leave much to be desired, even then the physician is not ensured against the commission of grave errors in prescribing. Without further study he must often rely upon the friendly hand of the professional pharmacist to correct his mistakes.

Here, too, then, the question is one of selection, of just how much will suffice in a field which is occupied by an allied profession.

There are great differences of opinion in regard to instruction in *Therapeutics*. In teaching pharmacology the therapeutic uses of drugs must necessarily be considered in more or less detail and pharmacological discoveries harmonized whenever possible with clinical practice. It is, therefore, necessary that the teacher of pharmacology shall be familiar with clinical work and with the actual effect of drugs and poisons on human beings. It is not necessary, however, that he should be an active practitioner, and it is only a man of unusual powers and exceptional training in science who can successfully combine practice with the demands

made on the pharmacologist of the present day as an investigator and a teacher. In all the leading universities of the world it is becoming more and more the custom for teachers of physiology, anatomy, pathology, physiological chemistry, and hygiene to devote themselves wholly to the duties of their chairs, and this practice will prevail more and more among pharmacologists as the wealth of medical foundations increases. No one individual, even if he has the widest clinical experience, can hope to teach the whole art of therapeutics. Is it necessary to attempt this? Is not the clinical teacher who is well grounded in the fundamental sciences the only one who can rightly train the medical student in the correct choice of drugs and other agents whose employment falls within his province?

Who, for example, can better teach the student how to treat the various acute and chronic forms of skin disease than the dermatologist; who better to treat the diseases of young children than the pediatricist; who better the details of drug application in diseases of the eye, throat, and nose than the specialist in these branches; who give wiser counsel in the use of drugs, foods, and other agents in the wide field of the internist than he who daily grapples with difficult problems in the cure and alleviation of disease? A practical mastery of therapeutics can only be obtained from contact with these men and their work.

In a limited way, a special course in *practical therapeutics* in the field of internal medicine may be given in a medical school, and it is of great assistance to the medical student who is obliged to enter upon practice immediately and without the advantages to be derived from a year or two of hospital practice. A course of this kind is a part of the curriculum of the Johns Hopkins Medical School and is given by an instructor in clinical medicine. It occupies a period of 15 weeks and consists of lectures and demonstrations given twice a week; as stated in the announcement of the gentleman in charge, this course comprises the clinical study of a number of the more common and useful drugs, their dosage, administration, and effects, methods of prescription-writing and illustrative formula, demonstrations of practical therapeutic measures, the use of hydrotherapy, the preparation of simple and useful forms of diet, the care of patients considered from the nursing point of view, the treatment of various emergencies and of special diseases by climate, rest, and other practical procedures.

The clinical work of the third and fourth years affords abundant opportunities for further training in practical therapeutics.

This brings me to the subject of *lectures and recitations or conferences*.

Some didactic teaching, be it in the form of lectures, recitations or conferences, is necessary in most, if not all, branches of medicine. In these exercises, the teacher not only clears up doubtful points and summarizes scientific evidence, but he also has an opportunity to so direct "the unwary understanding" of the young, as Sir Thomas Browne has it, that some perchance will escape intellectual sclerosis at forty.

My own experience with students has led me to believe that they profit most if they have first read their textbooks before attending a lecture on a given subject. The teacher's own experience is that he derives most advantage from a consultation with a specialist in some

other branch of science when he has first informed himself on the points at issue. It is then that a short talk with a man of wide experience easily clears up an obscure point. The student should be put into a similar attitude of mind by proving to him that he will get more out of an hour with his teacher than out of an hour with his books at home. If the subject under discussion is one that is well treated in textbooks, the established points may be passed in rapid review and then the latest researches, the newer theories brought out by the instructor. Whenever it is possible to do so, demonstrations and experiments should be used to illustrate the points under discussion, and these may be given either during the talk or immediately after.

No matter how well a textbook may be written, the teacher who is himself a worker in the laboratory and who follows attentively the researches of his contemporaries, will be able to clear up doubtful points and also to daily anticipate the author's second edition, for the last chapter of a textbook is hardly completed before the first needs revision. Aside from this, he is likely to have the advantage of the author of the book in certain fields, for no man is able to cover the whole ground with equal authority.

Now as to the student's part. I hold that only the laboratory work and attendance on such demonstrations as are of the highest importance should be obligatory. With such attendance and diligent reading of the best textbooks on the subject, the student will be able to bring himself up to the "pass" mark, since the examination should only cover the essential points, aiming like the later State examination to test and insure an average of attainment and an ability to make use of acquired knowledge. Of course the student will not in this way get the utmost possible out of the course, but to do this may not be a part of his plan of study.

He should be plainly told that he need not attend the lectures and recitations unless convinced that he will profit by them, and the head of the department and his corps of assistants will surely be above any small resentment when the student accepts this permission in good faith. The mutual attitude of teacher and student is of far more importance than rigidity of examinations or any tests or credentials whatever. I firmly believe in the liberty of both teacher and student. It is but fair to require of the former that he be a worker in some part of his field, and that he shall meet with enthusiasm and give his best to those who elect to go deeply into the subject as well as to do his duty to those who choose only the minimum or required work.

The immediate result of this frank understanding between teacher and student will be that the latter is free to give additional time and energy to some other line of work for which he may have a decided bent. But much more, he has the freedom of personal choice, with all the development that it brings to one who understands his own mental habits and needs. Petty and irritating restraints are removed and also the undue weight of authority sometimes attached to a curriculum supposed to be the result of the wisest judgment of his elders. We are apt to forget that we are dealing with men and women of some maturity whose plan for their life-work is made and who have a clear idea in general, of what their time is worth. They should have, as Bowditch, Mall, and other writers on this subject have pointed out, the advantages of an elective system and also, I maintain, have some freedom as to method of work in the field chosen.

Have childish restrictions, such as marking for daily attendance, and all the hateful machinery of the factory time-card system, by which some teachers attempt diurnal estimates of the student's mental status, resulted in such a remarkable elevation of the average student, that we should cling blindly to our present system?

As to *examinations*, that "necessary evil," I believe it will be admitted that, in subjects like that now under discussion, they should not be conducted as if the student were intending to make a specialty of each branch. They must be fair to the class as a whole. In my own opinion, a combination of written and oral insures the best results. Personal knowledge of the student's laboratory work, and also of the intelligence shown by him in recitations, is of great importance in enabling the instructor to judge of a student's right to his pass certificate. The ideal examiner for a given student is not always the man who has taught him, but may well be a specialist of equal rank in some other university. Such a change, so stimulating to the intellectual independence of the student, and so broadening to the teacher, could only be based on a better agreement than now exists in our country as to the teaching of a given branch in schools of equal grade. As long as faculties issue diplomas, they assume a responsibility toward the world of learning. How they shall discharge this duty is too large a subject for full discussion here, but it is very desirable that the method used shall involve a minimum of worry and strain on the part of the student, and of police duty on the part of the teacher.

THE UNIT SYSTEM OF LABORATORY CONSTRUCTION.

By CHARLES S. MINOT, LL.D.,
of Boston, Mass.

It is the usual custom to plan a laboratory building with a series of rooms adapted to particular needs, so that there shall be large rooms for large classes, smaller rooms for more special work, and private rooms for the instructors, places for apparatus and so forth. Undoubtedly an excellent building may be thus designed, and one well adapted for its original purpose. The suitability of any such building must, however, diminish more or less steadily as the years go by, for the simple reason that science changes, and its advance involves new changes in the teaching, changes of subject, of method and of apparatus, and it often happens that an old laboratory can meet the new demands but unsatisfactorily. Such difficulty arises especially, when any branch of science develops so much that it must for teaching purposes be differentiated into two, or three, or even more separate courses of instruction, each requiring special conveniences for its giving. Thus we have seen histology differentiated from anatomy, and making demand for quarters of its own, separate from the dissecting and with other conditions of light. Or again (an example), bacteriology represents an even greater differentiation from pathology, and insists on new laboratory accommodations. There is, too, a second factor, which constantly tends to render every laboratory inadequate, namely, the increasing growth of the medical schools in numbers. I am not acquainted with any statistics showing comprehensively the rate of this growth, but it is certainly rapid. These two factors, together with the conscientious effort to improve the quality of instruction, have led to an intense demand

for new laboratories, and now at this school, now at that, one hears of a new and costly building. We expect that many new laboratories for medical uses will be erected during the next few years.

Under these circumstances it becomes important to decide what design of the architect will be most likely to secure a building permanently available through the shifting needs of the future.

Now there is a class of buildings allied to laboratories, which, when well planned, allow for future enlargement, to wit: public museums. Formerly these were designed very much as laboratories now are, but at present a museum design is not considered good unless it is based upon a museum unit, *i. e.*, the floor-area covered by a single museum exhibition-case plus the necessary space around it for visitors. All the rooms are made multiples of this unit area. The other indispensable condition is sufficient lighting. If a museum is constructed upon these two fundamental principles, its rooms can all be used indifferently as work-rooms or exhibition rooms, or when it is enlarged the cases can be moved about each as a whole, and the entire museum easily rearranged.

This same conception of the unit, by multiples of which the dimensions of all the rooms are to be fixed, may be applied to laboratory construction. Although I know of no instance in which this unit system has been actually utilized for a laboratory building, I nevertheless venture to think that it is advantageous and practical.

It seems to me that the proper laboratory unit is the space necessary for a single student doing elementary laboratory work. The space must fulfil four requirements—it must offer room for the student to sit or stand and for others to pass by, it must offer room for a work-table, it must offer room for storage, and, finally, it must be abundantly lighted. The estimate of the floor-area for such a unit will necessarily vary, but it is likely to be about 20 square feet, which allows a table top 4 feet by 2 feet, and a space 4 feet by 3 feet for the student and for passage. It will also permit the table to have, say, two drawers and a locker below them, making a tier about a foot wide, and still leaving space for the student to sit comfortably at the table.

Next we may conveniently construct our units in pairs, that is, make tables for two students each, the drawers and lockers being placed at opposite ends of the table. This type of table is of course already often seen. Such a double unit may well serve for a single advanced student, or special worker, and for those cases, in which as often happens, two students make an experiment in partnership. A pair of students also can advantageously utilize a single window.

After fixing the size of our unit we must decide upon the number of units which should be taken for a single room. There are here two principal alternatives between which we may choose—the adoption of large laboratories or of a series of small laboratories. The choice is between keeping the students in large classes and dividing them into small sections. Personally I can advocate only the latter choice and must plead for it very strongly. In a large laboratory with 75 or 100 or more students, the noise and confusion are necessarily great, and the detailed supervision of the work is extremely difficult. If the students are subdivided into small sections, these and other difficulties at once vanish, and if each section can be assigned a separate room it may be put under the charge of a special instructor who shall be personally responsible for the work of that

section. Thus each assistant can be given a certain independence and the sense of opportunity with the accompanying responsibility will tend to improve the quality of his teaching. He can be directed to carry his section over a certain part of the subject in a given time and left free to accomplish the result. If the section is small enough the work can be interrupted for an explanation, a direction or a quiz, and the students will ask more and better questions than in the large laboratory, where the many listeners embarrass them, and where they may not find always the same instructor at hand. Finally, the instructor can learn the personal qualities and needs of the men in a small section and establish personal relations with the individuals. It should never be forgotten that such personal relations are the most important factors in efficient teaching. It might be urged against the position here taken that the class could be divided into sections in a large room, but my experience convinces me that such a scheme is utterly impracticable.

There should, I believe, be a unit room adapted to a comparatively small number of students, and the laboratory should consist of a number of such rooms, and nothing else except the necessary passage-ways and lecture rooms. A unit room can serve without change for a smaller advanced class. It could be divided by temporary partitions into two or more assistants' rooms, or fitted up for a collection of specimens, apparatus or books. Finally, when the necessity for enlargement arises, it will be necessary only to add so many new unit rooms as may be desired, and as the rooms are all alike they may be interchangeably utilized as convenience dictates.

As to the size of the unit room, I am inclined, after considerable deliberation and discussion, to fix it at 24 students, which seems to me quite the maximum number that one teacher can properly supervise and direct in a practical laboratory course. Such a room would, however, be somewhat larger than 24 unit spaces, since there must be provided additional room for various fittings for common use, such as sinks, lockers, apparatus cases or tables, and also a place for the instructor's personal use. This would make a room of about 800 square feet of floor space. Such a room is probably more commodious than has been regarded hitherto advisable, but it is not more than should be provided now that the value of laboratory work is so thoroughly appreciated that it has become the essential part of the curriculum in medical science in all our good schools. Moreover, such a unit room could be used by at least two sections, coming at different hours of the day and thus be made to provide not for 24 but for 48 students.

As to the general disposition of unit rooms the best plan will probably be found to be that of long corridors with rooms on each side, after the manner so common in large hotels. The provision for staircases, toilet rooms, etc., may well be left to the architect, and to the decision of the needs in each special case.

The suggestion of the unit system is made only in general terms, thus leaving open for further consideration the exact size of the unit spaces and the exact size and shape of the unit rooms. These dimensions may well vary, and be more or less liberal according to the standards and resources of each medical school. But quite aside from these details, the adoption of the unit system seems to me well calculated to diminish the difficulties of both the planning and maintenance of laboratories for medical instruction and research. A

building on the unit system would not be more expensive than one of irregular plan, although it would offer greater advantages.

METHODS OF TEACHING GYNECOLOGY.

By HOWARD A. KELLY, M.D.,

of Baltimore, Md.,

Professor of Gynecology in the Johns Hopkins University.

THE question as to the best methods of teaching any particular branch of our art is always one of burning interest, which should command the serious attention of teachers everywhere. Such a topic is also especially timely at this juncture, inasmuch as while, on the one hand, gynecology has now been taught regularly in various schools for a quarter of a century or more, and the methods of teaching gynecology have largely settled into well-defined ruts, on the other hand the evolution of scientific pedagogy has in the same period taken remarkable strides. It behooves all teachers, therefore, to question their systems and to decide whether they are really advancing on the best lines, in accord with what is recognized as good teaching in schools and colleges.

I believe that gynecology is, as a rule, very badly taught, and the medical student gains but little from this part of his course. This fact would be evident at once to anyone familiar with thorough scientific methods of teaching employed in other departments; but, unfortunately, the object-lessons of this sort in America are still few and far between.

Before we can decide what are the best methods of teaching gynecology we must consider a few of the difficulties in the way of securing anything like a consensus of opinion among the teachers.

And the first of these difficulties lies in the fact that so many schools have reorganized their plans of instruction in extending the two-years course to one of three years, and others the three-years course to four.

Advanced as the University of Pennsylvania has ever been in the lines of medical instruction, my own class was the first which graduated as a class with three years of compulsory study. As a rule, the professor of gynecology, continuing on from the old system into the new, made no corresponding change in his method of teaching to meet the altered conditions.

Another even more serious difficulty, and one which will, I believe, in the end, swamp gynecology as a specialty in the sense in which it has been practised, is the encroachments of the general surgeon in the field of abdominal surgery, leaving the gynecologist no particular settled ground which he can consider as peculiarly his own. It is foreign to my purpose to consider this question here or to assume the prophetic role, but I may briefly state my conviction that the unification of surgery brought about by the general adoption of the principles of asepsis leaves the barrier between general surgery and gynecology a purely artificial one, and one which must inevitably, sooner or later, be broken down. My advice, therefore, to all gynecologists is to study general surgery and become general surgeons first.

Three classes of men come to me for instruction in gynecology, and I feel obliged to provide to the best of my ability for each. They are:

I. Students preparing for graduation.

II. Postgraduate students revisiting schools for better equipment.

III. Graduates desiring to become specialists.

I. Students preparing to take the degree of doctor of medicine. How much should a student know at graduation? or how little may he know?

I think the tendency of most of our schools is to give entirely too much instruction in this purely special branch. One year's instruction is ample, even in a course graduated to extend over 4 years. This leaves the student free to devote more time to the fundamental branches and laboratory courses in general medicine and in the principles of surgery.

But few students ever become gynecologists, and it is a waste of valuable time to treat the whole class as if they were working with this end in view. I shall refer later to the training necessary to build up a specialist.

In the last year when medical specialties are taken up in the natural order after a thorough preliminary training in the fundamental branches, from 3 to 4 hours a week may be devoted to the class in gynecology divided as follows:

1. History-taking and ward work, attending to dressings and removing sutures, and studying the sequels of operations, the convalescence.

2. A touch course once a week in which gynecological diagnosis is taught with the patient preferably under anesthesia.

3. An hour a week in the pathological laboratory studying scrapings and cultures and examining gross specimens.

4. Watching gynecological operations, the class divided into small sections.

5. Lectures.

I think the day for teaching gynecology by performing operations in an amphitheater before a large class of students has long since gone by. The students see practically nothing of what is going on, absolutely nothing in a deep, abdominal, or vaginal operation, and their very presence is a serious menace to the life of a patient.

The history-taking, the ward-work, the touch-course, all of which demand personal instruction, are the most valuable methods, bringing student and patient together, as they must meet in the natural course of events after graduation, and carrying the student up to the point beyond which he will not be apt to go, that is, up to the point of deciding upon the line of surgical treatment to be followed.

It must be borne in mind that, with our present conception, gynecology is essentially a surgical specialty, and making a diagnosis of a gynecological affection means, as a rule, an operation, while, with the vaguer methods of diagnosis of our predecessors, the very uncertainty allowed a delay for weeks, or months, during which time all sorts of so-called palliatives were employed, a line of treatment easily carried out by the general practitioner. I well remember the first instructions I had in a special course, when all I learned was to give the woman much pain by the examination, and to paint the vault of the vagina with Churchill's tincture of iodine in one case, and the next woman, without rhyme or reason for the change, with a carbolic acid and chloral mixture, and so on *ad infinitum*, completing each treatment with a ball of absorbent cotton. Many were the cases of "cellulitis" which owed their origin to such a course of treatment, associated with "intrauterine applications."

I cannot dismiss the touch course without urging that the number who make the examination should be

limited to several working under the watchful eye of the teacher, lest harm be done.

The early recognition of cancer as taught by the study of endometrial and cervical scrapings in the laboratory (perhaps the most important function of the teacher of gynecology) constitutes a leading feature in my own teaching as ably conducted by Dr. Thomas S. Cullen.

The use made of the lecture-room should depend upon the lecturer; if he is an inspiring teacher who well comprehends the modern definition of a teacher, not as one who talks volubly, but as "one who causes another to know," he may make his lectures associated with demonstrations and specimens, diagrams, and lantern-slides, a great attraction to the students. If he is a poor, dry talker he would better relegate this part of his work to a good quiz master and confine himself to the more practical lines of teaching.

"Seeing operations," especially the major gynecological operations, is perhaps the most abused of all methods of teaching. It is utterly useless for the student to see over and over again a hysterectomy or an ovariectomy which he will never do himself, and which, if he did attempt to do, it would be of but slight service in making him a safe operator. What he most needs to see repeatedly are the various minor operations which he may have to do, such as curettage and suture of the relaxed vaginal outlet.

It may be more convenient and profitable to divide the class into small sections and to double or even treble the amount of instruction in a given space of time. This involves repetition with each succeeding group, but it saturates the students for the time being with the subject and brings them individually closer to their work.

II. The plan of teaching for post-graduates must, as far as practicable, imitate the laboratory methods so widely used in other departments. Lecturing must be subordinated to demonstrations *in animâ vivâ*. The place of the lecture is a short informal talk about topics with which the hearers are not likely to be familiar, which are about to be demonstrated in practice.

The operator will then do well as he goes along in his practical work at the operating table if he remembers the needs of the bystanders and tells them from time to time precisely what he is doing and his reasons for doing it.

I do not consider it right, in the interests of the patient, to utilize men who enter a clinic for a few weeks only, as assistants in important operations.

Unfortunately, too, for the same reason (the patient's rights) only a limited number can be allowed to examine the patient beforehand. The surgeon must try to supply this want as far as possible by giving graphically both the history and results of his own examination.

A great need which we feel most keenly in this country is that of female cadavers enough to supply the demand for special dissections and for demonstrating operations to both students and post-graduates. An abundant supply of such material would greatly enrich our teaching facilities.

It is my own custom to receive post-graduates as on-lookers at any time in the course and for any period, to provide for them abundant demonstrations of the various gynecological operations, and an opportunity to study scrapings in the pathological laboratory.

III. I come now finally to a class which I think has not yet received sufficient attention in other clinics, a class, however, which I am personally inclined to

regard as really the most important of all to us teachers, that is to say, those men who are to be built up to become specialists in gynecology. In order to train a man this way the chief must be careful to select men who have real surgical ability; he must keep them for periods of from four to six or even eight years; they must receive exceptional opportunities in the operating-room (some of my assistants perform upwards of two hundred abdominal operations while acting as first and second assistants in the hospital). The chief must treat his capable men with the utmost generosity in this particular.

He must further supervise the development of a good man in his laboratory work, in his ward work, and in his teaching, and finally often end by sending him abroad to give him that assurance in his own powers which often only comes after witnessing the work of others. One of the greatest pleasures of my life has come from the association through a period of years, with just such men who have afterwards gone elsewhere to render distinguished services.

The man who in this way looks not only to his own success but endeavors to stimulate and to develop others, much as he would himself have wished to have been treated early in his career, will not only command the respect of his own generation, but will surely be reckoned by the men who follow him among those who have done the most to promote the best interests of his specialty.

The following is a summary of the course in gynecology as conducted for undergraduates in the Johns Hopkins University and Hospital:

At the Johns Hopkins Medical School the fourth-year class is divided into four sections, each of which devotes a large portion of its time for two months in turn to practical work in medicine, surgery, gynecology, and obstetrics, while in all those subjects lectures and quizzes are given to the whole class throughout the year.

The graduating class of last June numbered about 40.

The instruction in gynecology during the university year 1899-1900 was conducted as follows:

Lectures.—In gynecology, two didactic lectures were delivered each week to the fourth year students. Dr. Kelly lectured once a week, and Dr. Russell once, and between them the whole range of the subject was gone over.

The lectures were illustrated by blackboard sketches, diagrams, pathological specimens, and, whenever practical, by the demonstration of cases. Quizzes were occasionally substituted for the lectures, in order that the instructors might keep informed as to the students' progress.

Clinics.—Dr. Kelly operated three days a week throughout the year, and Dr. Russell one day.

The operating room was open to as many of the class as cared to attend, and the gynecological section was required to be present.

Before and during the operation the cases were discussed, opportunity given for a limited number of the students to make examinations under ether, and so arrive at their own diagnosis.

Special care was taken to impress the students during the operation with the importance of careful aseptic technic.

Ward Work.—To each member of the gynecological group several cases in the public wards were assigned during their two months' service.

The students took the histories of these cases, made the examinations under the supervision of the resident, witnessed the operation, and followed the after-treatment progress of their cases.

Rounds were made with the gynecological group by the resident twice a week, during which dressings were made, and the reasons for the treatment adopted explained.

Touch Course.—Once a week throughout the year a "touch course" was conducted by Dr. Russell. Here, from 3 to 6 dispensary patients whose condition without an anesthetic was uncertain, were carefully examined under ether by two to four members of the gynecologic section who made their diagnosis under Dr. Russell's direction. This course has for years proved of the greatest service to students.

Experience has shown that it was better for all concerned that the gynecological dispensary be conducted by a limited number of experienced men, hence this department has not been opened to the undergraduates.

Pathology.—For 4 months during the year a course in gynecological pathology was conducted by Dr. Cullen.

After an introductory lecture at each exercise sections were given out for microscopic study. Whenever possible the history of the patient, the operative interference, and the subsequent treatment were reviewed, while the preparations were being examined and demonstrated under the microscope. The pathological laboratory was open throughout the year for any students who cared to carry out original investigations.

Examination.—At the close of the term a final examination, both practical and written, was held, covering the work of the year.

THE METHOD OF TEACHING PHYSIOLOGICAL CHEMISTRY.

By R. H. CHITTENDEN, Ph.D.,
of New Haven, Conn.

Professor of Physiological Chemistry in Yale University.

In considering the methods of teaching physiological chemistry it is important to bear in mind that this department of biological science is in many ways more closely related to physiology than to chemistry; indeed physiological chemistry is to be considered as an integral part of physiology. Physiology deals with function, with the chemical and physical processes of living organisms, and the only reason why, in the minds of many persons, physiological chemistry stands by itself is the fact that the methods of work are essentially chemical. To be a physiological chemist a man must be a thorough chemist, well trained in chemical methods and well versed especially in the facts and theories of organic and physical chemistry. But while all this is true, it must not be overlooked that the ultimate object of all work in physiological chemistry is the elucidation of physiological phenomena. The questions to be settled are physiological questions, while the methods of work are essentially chemical. Obviously, then, the physiological chemist who hopes for a thorough understanding of the subject must be as well trained in physiology as in chemistry. Indeed, he should be a physiologist, as the term is ordinarily used, and at the same time possess an intimate and concise knowledge of chemistry and its methods. There are, to be sure, many purely

chemical problems, in both organic and physical chemistry, solution of which may throw light upon certain physiological problems: the chemical constitution of many organic substances occurring in the body is a case in point. Such questions are purely chemical, and for their solution require chemical knowledge only, although their elucidation may prove of great advantage to the science of physiology. The point the writer wishes to emphasize, however, is that physiological chemistry, while requiring a thorough knowledge of chemistry for its study, is something more than a mass of accumulated chemical data, and that its proper understanding involves a broad and thorough grasp of physiological principles. In order to rightly interpret the many and varied chemical facts which the student of physiological chemistry is called upon to study there must be, first of all, an accurate comprehension of the physiological significance of the facts in question, otherwise the work loses its chief value.

From the foregoing statements it will be evident that the study of physiological chemistry should be undertaken only after the student has acquired a working knowledge of chemistry and physics, and has received some training in general physiology. With this knowledge as a basis he is then prepared to pass on to the more thorough and experimental study of chemical and physical physiology. The two should go together, bearing in mind that what is desired is a broad knowledge of physiology. The writer has no sympathy whatever with the so-called short courses in physiological chemistry which deal simply with isolated experiments and groups of chemical reactions characteristic of the various proximate principles. To be sure such courses may be better than nothing, but they do not deserve the title of physiological chemistry. What is needed, on the other hand, in any course in physiological chemistry worthy of the name, is a thorough presentation of those chapters of physiology which are essentially chemical in nature, the principal and underlying facts to be worked out in the laboratory and supplemented by didactic lectures, demonstrations, and textbook recitations. In the writer's judgment it is only by this method of treatment, viz., by considering the subject as a part of physiology, to be studied in connection with related topics more physical in nature, that the full bearing of the experimental work can be made clear. For example, take the chapter on saliva and salivary digestion. The common method of treatment is for the chemical reactions of saliva, the conditions favoring the amylolytic action of this fluid, and the chemical nature of the products formed in amylolysis to be studied by themselves as a part of physiological chemistry, while the secretion of saliva, the influence of the nervous system on secretion, the histological changes of the gland-cells incidental to secretion, etc., are treated quite independently, and frequently at another time by a different instructor, under the head of physiology. How much better and how much more satisfactory to the student for the entire subject to be considered at one time, or as closely related matter requiring practically simultaneous treatment. Thus, it is an easy matter to not only show each student the influence of stimulation of the *chorda tympani* on the flow of saliva from the submaxillary of the dog as illustrating secretion, but at the same time the chemical composition of the fluid can be compared with that resulting from stimulation of the cervical sympathetic. The influence of alcohol, ether-vapor, etc., on the secretion of human

mixed saliva can be easily compared with the secretion resulting from simple mastication of some tasteless substance like rubber, not only by noting variations in volume for given periods of time, but in addition by studying the difference in chemical composition, and more particularly by demonstrating the differences in amylolytic power, thereby obtaining experimental evidence of the influence of the form of the stimulation upon the chemical composition and amylolytic strength of the secretion. By such a method of study, added to the usual demonstrations of amylolytic action, etc., the student is made to feel that his work in physiological chemistry is an integral part of his physiological training, and the subject acquires an interest it would not otherwise possess.

Again, in the study of gastric digestion it is not sufficient for the student to demonstrate merely the well-known facts regarding pepsin-acid proteolysis, but he should see for himself the production of a gastric fistula on a good-sized dog, collect gastric juice under different conditions and forms of stimulation, study the chemical composition of the secretions, determining the percentage of free and combined acid and the extent of their proteolytic power, and supplement these observations by the chemical examination of stomach-contents from man in health and in disease. Further, as a part of his chemico-physiological training he should study the character and extent of absorption from the stomach (ligated at the pylorus) and at the same time gain some practical experience as to the influence of such agents as alcohol, etc., on the secretion of gastric juice, both from a qualitative and quantitative standpoint. Again, not only should the chemical properties of the several products of gastric digestion be studied with great thoroughness, but likewise the physiological effect of these substances when injected intravenously. The influence of peptone and albumoses on the coagulation of the blood, on arterial pressure, as lymphagogs, and their action on the kidneys, are all subjects which may appropriately be studied experimentally with the products which the student has himself prepared in his work on digestive proteolysis. It is by such methods of study that physiological chemistry can be made to yield the best results; by giving to the subject its true position as an integral and essential part of physiology.

As another illustration take the glycogenic function of the liver. How incomplete and unsatisfactory to limit the study of this subject to the mere preparation of glycogen from the liver and a demonstration of its more common chemical reactions, as is so frequently done! How much more instructive and satisfying to demonstrate in addition the influence of diet upon the yield of hepatic glycogen, to study by micro-chemical methods the distribution of glycogen in the liver-cells, to demonstrate the relationship between the glycogen-content of the liver and the amount of sugar appearing in the urine after puncture of the floor of the fourth ventricle, to show by experiment on a fasting dog (with liver free from glycogen) that the injection of phloridzin is followed by a large excretion of sugar in the urine, thus indicating that the sugar can come from something other than carbohydrate, and lastly to trace out in the phloridzin dog the relationship between the excretion of nitrogen and sugar through the urine, thereby obtaining data in conformity with the theory that the sugar comes from the breaking down of the proteid.

It is, however, in the chapter on the urine that one commonly finds the most conspicuous lack of appreciation of

the true scope of physiological chemistry. The average teacher seems to rest contented if the student simply becomes familiar with the methods of separating the more common urinary constituents and learns their chief chemical reactions, adding to this a little experience in the testing for abnormal constituents such as albumin, sugar, bile-pigments, etc. Occasionally, too, a little experience is gained in the quantitative estimation of total nitrogen, urea, albumin, sugar, etc., but more generally with special reference to their clinical application in hospital-service, etc. Too little attention is given to the physiological axiom that the chemical study of the urine gains its chief importance from the light which it throws upon the processes of metabolism, both normal and abnormal, going on in the body. Here lies a great field, full of richness and one which should be explored more or less thoroughly by every student of physiological chemistry. Let the student be trained to make a complete quantitative analysis of the 24 hours' urine determining total nitrogen, urea, uric acid, nitrogen in the form of ammonia, sulphuric acid in the form of pre-formed sulphate and as combined sulphuric acid, total phosphoric acid, earthy phosphates, chlorids, etc. Let such a series of analyses be made by a class of students—say twenty men—and the results tabulated on the blackboard. By so doing a series of figures are obtained from which many important conclusions can be drawn. With a record of the body-weight of the individual students, of the total volume of urine and specific gravity it is easy to see that the volume of urine and the excretion of nitrogen are quite independent of body-weight. Proteid metabolism as indicated by the amount of nitrogen, sulphur, and phosphorus excreted is found to be independent of the size of the body, while the ratio of uric acid to total nitrogen shows such variations as to suggest at once that uric-acid production must be independent of ordinary proteid metabolism. The proportion of combined sulphuric acid and the yield of indican throw light upon the extent of intestinal putrefaction, and in this way by a careful scrutiny of the results obtained by the students in the analysis of their own urine many points of great physiological interest are demonstrated, and in a manner to arouse interest and enthusiasm. Further, by putting the men upon diets of different kinds many other facts of value may be obtained. Thus, if one man is fed mainly upon a diet of roast beef with some bread and potatoes while his neighbor consumes an amount of sweetbread (rich in nuclein) equivalent to the beef taken by his neighbor, it makes an interesting study to compare the output of nitrogen, uric acid, and phosphorus in the two cases. By a scrutiny of the results the students see at a glance that while the total nitrogen egested may be essentially the same, the nuclein-containing diet results in a much larger output of uric acid and phosphorus, thereby indicating the probable origin of uric acid, in part at least, in the nuclein molecule.

Again, in studying the extent of proteid metabolism in its relation to the amount of proteid food ingested, it is an instructive experiment for the student to determine the amount of nitrogen in his daily food, and likewise the amount of nitrogen in both the urine and feces for the 24 hours. In this way data are obtained as to the extent of digestibility or availability of the proteid portion of the diet in question, thereby emphasizing the distinction between the so-called food and that which is physiologically of service to the body.

Obviously, there are certain chapters of physiological

chemistry in which chief interest centers around the chemical facts themselves, but even here it is not a difficult matter to bring to the surface the bearing which these facts have on the broader physiological and biological questions which surround us on all sides. For many reasons the beginner in physiological chemistry devotes his attention first to a chemical study of the various forms of proteid matter, but here the significance of his work in relation to physiology may be made clear by a series of illustrations showing the importance of proteid as an integral part of all cell protoplasm, of its constant presence as an essential component of all living tissues, and the extent of its decomposition in the living human body. By calling attention to the fact that a man of average body-weight excretes about 35 grams of urea per day (with 46% of nitrogen), and that this must of necessity come primarily from the breaking down of proteid, we have a sufficient argument for the physiological importance of proteid, and at the same time a striking illustration of the value of a thorough study of the decomposition products of proteid by oxidation and otherwise, with a view to understanding, so far as possible, the chemical constitution of this complex molecule and the changes which it undergoes in the body in the processes of catabolism, prior to its final excretion as urea.

Again, in the chemical study of the inactive tissues of the body—viz., the epidermal, connective, cartilage, and bone—where the facts to be gleaned are mostly chemical, it is still possible to bring out with great clearness the bearing which these chemical facts have upon the genetic relationship of the tissues and their origin from the mother proteid.

This, then, is the point I would emphasize in the method of teaching physiological chemistry—viz., to so teach the subject in the lecture-room, class-room and laboratory as to emphasize in every possible manner the relationship of physiological chemistry to physiology; or, in other words, to treat each subject under consideration broadly and with due regard to its physiological significance and relationship. In no other way can the study of physiological chemistry attain the importance it merits, or exert that influence as an educational factor which its close relationship to medicine and biology warrants.

TEACHING OBSTETRICS.

By J. WHITRIDGE WILLIAMS, M.D.,

Professor of Obstetrics, Johns Hopkins University, Baltimore.

THE ideal method of teaching obstetrics would be to divide one's students into two groups, according as they expect to practise that branch of medicine in their future professional work, or as they study it merely as a part of their general training.

To the former an extended course could be given and many subjects considered in detail which are of but little interest to the average student, and facilities could be afforded for a large amount of practical work. While, on the other hand, an elementary course could be given to the second group, in which only the general outlines of the subject would be taught, together with a minimum amount of hospital work. For it appears to me that it is a great waste of energy for a student, who expects to devote himself strictly to internal medicine or to one of the purely scientific branches, to be obliged to devote

practically as much time to the study of obstetrics or surgery, for example, as to the subject in which he is particularly interested.

Unfortunately, these ideals, desirable as they may be, cannot be attained until the methods of medical education are entirely revolutionized and a system inaugurated in which the individual student is permitted to elect, to some extent at least, certain branches of medicine to which he desires to pay particular attention. So that at present one must be content to instruct all students in practically the same way, no matter what their individual preferences may be, and limit one's aspirations to making one's course as profitable and practical as possible.

For the past two years I have attempted to differentiate my students to a slight extent, by affording increased clinical facilities to those who desire them during the summer months. I do this at the end of the third year by ascertaining which students are particularly interested in obstetrics, and then allow 12 of them, who have stood best in their class, to have the run of the wards for three weeks each. In this way each of the 12 students is enabled to see 20 or 30 women delivered, instead of 8 or 10, as the rest of the class. This plan has proved very satisfactory, as it solves the problem to a slight extent, and also affords a method of rewarding those who have done conscientious work.

Obstetrical instruction should be given in the third and fourth year of the medical course, and should consist of—1. Lectures. 2. Recitation. 3. Manikin work. 4. Laboratory work. 5. Demonstrations. 6. Ward classes. 7. Delivery of patients in the lying-in ward. 8. Delivery of patients in the out-patient department. 9. Clinical conferences or clinics; and 10. Examinations. The theoretical and laboratory work should be given in the third, and the practical work in the fourth year.

In considering the details of the course, I cannot do better than by practically repeating what I wrote two years ago for the Committee on Course of Study of the Association of American Medical Colleges.

1. LECTURES.

At present many teachers favor abandoning didactic lectures in favor of recitations and clinical conferences, but I believe that they still serve a useful purpose, but that their utility depends, to a great extent, upon the person giving them. If the teacher simply bases his lectures upon some standard textbook, I believe that he will best subserve the interests of his students by abandoning them, and allotting a certain number of pages or chapters of the textbook for recitation at each meeting of the class, which he will supplement by demonstrations of various kinds and freehand drawings upon the blackboard.

If, however, he has higher aspirations, and is able to avail himself of the recent English, French, and German literature, I believe that the didactic lectures will continue to play an important part in obstetric instruction, and will enable the student to obtain a rounded idea of the theory of obstetrics, four or five years in advance of the doctrines laid down in the latest edition of his textbook.

The lectures should be accompanied by as many demonstrations as possible, and the teacher should rely less upon carefully prepared diagrams and drawings, than upon plentiful freehand drawings upon the blackboard. The student may admire the former, but the latter he can reproduce in his notebook.

2. RECITATIONS.

A recitation hour should follow every third lecture, and the student questioned not only upon the work immediately preceding the recitation, but upon the work so far as it has been covered, thus necessitating a constant review of the entire subject.

The students should be encouraged to ask questions freely, and the recitations should be conducted as informally as possible, but at the same time a record should be kept of the work done, which should be considered in estimating the final standing of the student.

The recitation is almost as important for the teacher as for the student, as it enables him to emphasize and elaborate important points and discuss them with the students and frequently demonstrates how imperfectly he expressed himself in his lectures. The recitations should, therefore, be conducted by the teacher himself, and not be delegated to one of his assistants.

3. MANIKIN WORK.

Exercises upon the manikin should form an integral part of the obstetrical course; but their scope should depend, to a great extent, upon the amount of material which is available for clinical instruction. If there is a large lying-in hospital in connection with the medical school, it will be unnecessary to attempt to teach the technic of abdominal palpation, vaginal touch and internal pelvimetry upon the manikin, as it can be taught very much more satisfactorily upon the living woman. But if the clinical material is limited in amount, we consider it advisable that the students be taught the rudiments of palpation, touch and pelvimetry upon the manikin, so that they will know exactly what they are to do when they examine the patients in the wards, whereby clinical material is economized, and the patients saved considerable annoyance. For this purpose, the Budin-Pinard manikin is to be recommended.

The main object of the manikin work is to teach the various operative procedures, and each student should be obliged to perform all possible operations upon the manikin, at least once during the session.

The manner in which the work should be conducted must vary according to the size of the class. If it does not exceed 50 members, I believe it best to attempt to instruct the entire class together. This can readily be accomplished by employing three or four manikins, one to every 12 students, and having the professor at one and an assistant at each of the others. In this way, three or four men can be operating at the same time.

At the beginning of the hour, the professor should give an outline of the operation, its mode of performance, indications, etc., and then call upon the students to perform it under his supervision. While this is being done, it is well to quiz the class, and thus make the meeting serve a double purpose. Such meetings should last about one and a half hours, during which at least 12 men can operate upon each manikin.

If the class exceeds 50 in number, it will be necessary to divide it into sections. We believe that the professor should always take part in the manikin instruction; and, if it becomes necessary to divide the class, he should alternate between the sections.

4. LABORATORY WORK.

I consider it imperative that laboratory work should be included in the obstetrical course, as it is impossible for the student to grasp the subject intelligently, unless

he be more or less intimately acquainted with the minute structure of the organs of generation, and with the lesions associated with the various diseases, which may complicate the pregnant and puerperal condition.

Of course, many of these subjects are studied during the first and second years, in the courses upon histology and pathology; but owing to the immense field which must be covered in each of these branches, it is impossible to more than touch upon salient points, which are soon forgotten. It is, therefore, necessary that this field should be gone over again more in detail, and with especial reference to the practical side of obstetrics, and this can only be done by one who is particularly interested in this branch of medicine.

This work should be delegated to a special assistant, whose duty it should be to prepare the material for the class, and with the aid of the others, to demonstrate it to them. While this work is going on, the class should meet twice a week for one and a half or two hours. The sections should be given to the students at one meeting, when they must stain, mount, and study them. At the next meeting they should be described by the instructor, who should then go around the class and ascertain that the necessary points have been made out by each student. It is not advisable to give more than four or five specimens in any one week.

This work should be begun at the commencement of the year, and the normal anatomy of the genitalia and the development of the placenta thoroughly studied. When this is accomplished, the same hours should be devoted to manikin work, and after its completion, the pathology of obstetrics should be taken up. In this way, two meetings a week of one and a half to two hours each may be occupied profitably throughout the year.

If the class exceeds 40 or 50 in number, it will be necessary to divide it into sections of convenient size.

This work, of course, does not necessarily require special laboratory accommodations, as it may be done in the histologic, pathologic, or clinical laboratories, as may be most convenient.

In the following list are mentioned the specimens which may be profitably studied in this manner:

1. Labia majora and minora
2. Vaginal mucosa.
3. Longitudinal section of cervix, showing transition from cervical to vaginal epithelium
4. Transverse section of cervical canal, showing its arborescent structure
5. Endometrium of young girl.
6. Endometrium of adult.
7. Endometrium of old woman
8. Pregnant uterus, showing increase in size of muscle-cells
9. Involved uterus showing decrease in size of muscle-cells and degeneration of vessels.
10. Menstruating uterus
11. Uterine end of fallopian tube.
12. Central part of fallopian tube
13. Lateral end of fallopian tube.
14. Round ligament.
15. Ovarian ligament.
16. Infantile ovary.
17. Girl's ovary.
18. Adult's ovary.
19. Senile ovary.
20. Corpus luteum, fresh
21. Corpus luteum, eight to ten days old.
22. Corpus luteum, two to four weeks old.
23. Corpus luteum of pregnancy.
24. Ovary showing corpora fibrosa.
25. Ovary showing atresic follicles

26. Corpus luteum cyst.
27. Decidua, four to six weeks.
28. Decidua, four months.
29. Decidua reflexa (from abortion).
30. Early chorion, to show double layer of epithelium
31. Placenta, three months
32. Placenta, four months, if possible in connection with the uterine wall.
33. Normal placenta at term.
34. Normal placenta at term injected.
35. Uterine wall and fetal membranes outside of placental site.
36. Young umbilical cord, fetal end to show stalk of umbilical vesicle.
37. Umbilical cord at term.
38. Inflammation of decidua.
39. Early placental infarct.
40. Developed placental infarct.
41. Hemorrhagic placental infarct.
42. Normal fetal epiphysis.
43. Syphilitic fetal epiphysis.
44. Syphilitic placenta, fresh, tease out chorionic villi. Compare with normal.
45. Syphilitic placenta, hardened.
46. Hydatidiform mole.
47. Tubal pregnancy, to show decidual and placental formation.
48. Rachitic bone.
49. Osteomalacic bone.
50. Eclamptic kidney.
51. Eclamptic liver.
52. Eclamptic lung.
53. Puerperal infection, showing streptococci limited to decidua.
54. Puerperal infection, showing streptococci in the uterine wall.
55. Puerperal infection, showing streptococci in the broad ligament.
56. Puerperal infection, showing noninvolvement of the fallopian tube.
57. Puerperal infection, due to streptococci and putrefactive organisms.
58. Puerperal infection, due to putrefactive organisms alone.

It is apparent that any one who has carefully studied these sections will have a far better and more lasting conception of obstetrics than one who has not.

In addition to the normal anatomy, he will have precise and accurate information upon the ordinary diseases of the placenta, and will be able to diagnose fetal syphilis by the examination of the placenta and the fetal bones.

He will learn, for example, that the hydatidiform mole is not merely a myxoma of the chorionic villi, but that it presents marked changes in its epithelium, which places it in close relationship with the deciduoma malignum or syncytial carcinoma. He will also learn the true nature of rachitis and osteomalacia, and thus more readily understand the genesis of certain varieties of deformed pelvis. By studying the tissues from a case of eclampsia, he will learn that it is a disease not merely of renal origin, but that it is accompanied by lesions in the liver and other organs, which place it in a totally different light. The examination of sections from the various varieties of puerperal infection will afford most important indications for treatment, and teach the futility of cureting the uterus in cases of streptococcus infection, and the marked benefit to be derived from the same operation in those forms due to infection with putrefactive and other organisms.

These and many other benefits will accrue from the study of obstetrics in this manner, and we feel that its importance cannot be urged too strongly upon the teachers of obstetrics.

5. DEMONSTRATIONS.

Demonstrations should also play an important part in obstetric teaching. They should serve partly for the illustration of lectures and frequently should be given independently of them.

Every teacher should exert himself to obtain as many objects as possible which are suitable for demonstration. Many can only be collected gradually, such as frozen sections of pregnant and parturient women, as well as of the fetus and young children of various ages for demonstrating the fetal and infantile pelvis and the relations of the generative organs, series of ova at various periods of development, placental diseases and abnormalities, and many other anatomic and pathologic specimens.

Among the various aids for teaching which can be bought at any time, we may mention: Trammond's three specimens of dissections of the female perineum and pelvic floor, which greatly facilitate the demonstration of this difficult subject; Tarnier's bronze pelvis, manufactured by Collin, of Paris; Edgar's aluminum pelvis and blackboard, manufactured by Reynders, of New York; Edgar's models of the pregnant uterus at the several months of pregnancy, also manufactured by Reynders. These models are of great value, in that they enable us to give the student an accurate conception of the exact size of the uterus at each month of pregnancy. Edgar's casts illustrating the immediate repair of the lacerated perineum are also very valuable, while his leather uterus is a useful adjunct to the manikin, and enables us to teach the student how to pack the uterus with gauze to check hemorrhage, and to sew up the lacerated cervix for the same purpose.

One of the greatest aids in teaching, especially in this country, where certain forms of contracted pelvis are rarely observed, is the series of 24 models of the various forms of deformed pelvis, prepared by Trammond of Paris. All of them are modeled exactly after celebrated examples of pelvic deformity in the various museums of Europe. An appliance, which is invaluable for demonstrating the genesis of the various forms of deformed pelvis, is the pelvis in "composition molle," manufactured by Trammond, which can be given any shape by the hands.

This list might be extended almost indefinitely, but we have referred only to such models and appliances as we consider essential.

Any one interested in this line of work is referred to the interesting article of Dr. J. C. Edgar, in the November and December numbers of the *New York Medical Journal* for 1896, which contains many valuable suggestions.

6. WARD CLASSES.

For teaching the technic of examining pregnant women, the class should be divided into small groups, whose size must depend upon the amount of clinical material available. Each student should be carefully drilled in the principles and practice of asepsis, taught to diagnose the position and presentation of the fetus by abdominal palpation and vaginal touch, impressed with the necessity of measuring the pelvis both externally and internally, in every case, etc. They should also be required to take the histories of patients in the ward, to make the necessary urinary examinations, and to accompany the professor or the resident obstetrician at the daily visit.

They should also be required to examine the puer-

peral women just before they are discharged from the hospital, so as to become acquainted with the condition of the genitalia in the latter part of the puerperal period.

Each student should be required to examine at least ten pregnant women, not including the cases seen during labor, before being allowed to come up for the final examination in obstetrics.

7. DELIVERY OF PATIENTS IN THE LYING-IN WARD.

A small number of students, preferably two, but certainly not more than four, should be called to the ward to see every case of confinement. They should be required to examine the patient, both internally and externally, once during the first, and again during the second stage of labor. In uncomplicated cases one of the group should deliver the woman himself, under the guidance of a competent assistant.

A much larger number of students may be called to operative cases as onlookers. Each student should be required to see at least five cases delivered in the lying-in ward; for it is only there that he can learn the ideal method of conducting a labor case. A service of 150 cases yearly will be sufficient for a class of 100 students, provided four students were called to each case.

8. DELIVERY OF PATIENTS IN THE OUT-PATIENT DEPARTMENT.

An obstetric dispensary should be organized in connection with every medical school, and poor women delivered at their own homes by students under the personal supervision of an assistant, who should be accompanied by a trained nurse if possible.

The custom of sending two students alone to a labor case cannot be deprecated too strongly; for they are almost certain to fall into slipshod methods and fail to carry out the more or less rigorous technic which they have learned in the lying-in ward. But when they are sent to these cases under the charge of a competent assistant, who is prepared to demonstrate the case and to see that the rules of asepsis are strictly followed, we believe that the out-patient obstetric service will be quite as useful in training students as the lying-in ward, and perhaps more so, in that it teaches them to conduct a labor aseptically under all the disadvantages which are encountered in the homes of the poor, quite as well as in the ward with all its conveniences, and thus they are fitted directly for private practice.

The student should be required to visit the patients during the puerperium, say for the first five days and again on the seventh and tenth days, and should be provided with a fairly full printed history sheet in which he should be required to outline the more important facts concerning the case, which should be given to the assistant in charge after the last puerperal visit.

It should be understood that the instructor regards the return of the history sheet as an important matter, and that the manner in which it is filled out plays an important part in determining the final standing of the student. I consider that two cases carefully observed in this manner are quite as valuable to the student as ten cases seen in the usual way without supervision. Each student should be required to attend at least five out-patient cases; and a service of 250 cases a year would be sufficient to furnish cases for a class of 100 students, if two students conducted each case.

In large cities, a considerable part of the out-patient obstetric material is lost for the purposes of clinical in-

struction by the time consumed in getting the student to the case, especially when he lives a considerable distance from the hospital. To obviate this difficulty, one or more rooms should be provided by the department, according to the size of the service, in which two or more students should be kept on call at night, until they have seen their quota of cases.

9. CLINICAL CONFERENCES.

During the fourth year there should be a weekly meeting of the class, in which most of the teaching should be done by the students themselves. Here interesting cases which have been observed by the students are discussed. A student who has lately seen an interesting case should be informed a day or so in advance that he is expected to report upon it. When the class meets, he should read a concise history of the case, and then perform upon the manikin the operation which may have been required. The case is then discussed by the instructor, and the class questioned concerning more or less cognate cases.

At another meeting, a dead-born child and its placenta may be exhibited. Two students may be called upon to perform an autopsy upon the child to ascertain the cause of its death; to a third student the placenta may be given, with instructions to tease out some villi, examine them under the microscope, and ascertain if they present syphilitic lesions. This will consume about half an hour. Then the diagnoses are called for, and the history read by the student who observed the case, and it is attempted to bring the clinical history into accord with the anatomic findings and vice versa.

At another meeting, several ova of various ages may be given to as many students, who should carefully examine them and then report what stages of development they represent, and their reasons therefor.

Another very practical manner of spending the hour is to take three deformed pelvises and give each one, with a pelvimeter and a piece of paper to two students. Allow 15 minutes for measuring the pelvises, and then call upon one student in each group for the diagnosis, his reasons for making it, and the measurements upon which it is based. And ask the other how he would diagnose a similar pelvis in the living woman, and what procedures he would adopt to deliver her, etc.

Of course, this kind of work may be amplified to almost any extent, and is only limited by the amount of time and material at the disposal of the instructor.

10. EXAMINATIONS.

I do not believe that the standing of a student should be based solely upon the mark obtained in a written examination, but consider that it should also depend upon the character of his class work and the general impression which he makes upon the instructor; and that each of these factors should count equally in estimating his value.

At the end of the third year the student's standing should be estimated from three sources—written examination, recitations, and general class work. The value of the first two is readily estimated, while that of the general class work is of a more personal character, and therefore cannot be determined so accurately. It is based less upon the actual performance of the student than upon the general impression which one gains of him. Thus, many a student who can pass a good examination and answer fairly well at recitations, impresses one as an indifferent or poor man by the

manner in which he answers and asks questions, and by the way in which he appears to take hold of the subject; while, on the other hand, another student may pass a poor examination, but still show by his class work that he is really an excellent man.

In other words, I advocate basing a part of the total mark upon one's estimate of the personal equation of each student. In very large classes this, of course, is out of the question, and even in small classes one's estimate is not always correct. But any mistake in this respect can usually be equalized or corrected by marking the examination papers without knowing by whom they are written.

In the fourth year the standing should likewise be estimated from three sources—recitations, clinical work, and a practical oral examination at the end of the year.

In estimating the value of the clinical work, especial stress should be laid upon the manner in which the history-sheets are filled out and upon the general behavior of the student. The final examination should be conducted at the bedside or with the manikin, and an attempt made to test the practical knowledge of the student. At the same time questions should be asked of such a character as to give some idea of his powers of reasoning, instead of how well he can memorize a textbook.

Examinations of this character consume considerable time, and cannot be well applied to large classes unless conducted by several examiners. But where they can be carried out, I am confident that they afford the most satisfactory means at our disposal of ascertaining what a student is worth.

ON THE TEACHING OF PATHOLOGY.

By J. G. ADAMI, M.A., M.D.,

Professor of Pathology, McGill University, Montreal, Can.

THE first thought of all will be, as it was my first thought, when, unguardedly, I acceded to the editorial invitation to contribute to these pages under the above title, that, if any one, a teacher should be able to write about the teaching of his special subject. Yet, unless the teacher is satisfied merely to set forth his particular methods the matter is far from simple. Those particular methods depend in every case upon environment, opportunity, and the man. In the case of pathology they depend upon the general curriculum of the school—whether by tradition the subject is made a part of the second, third or fourth year's course or is spread over two or more years; upon the number of hours allotted; upon the extent to which the special pathology of different systems and conditions is taken up in the courses in medicine and surgery; upon the nature and extent of the course in bacteriology. In fact, just as every school differs in the details of its curriculum, so must the course in pathology vary in its details in order that it may dovetail into the rest of the teaching with the maximum of benefit to the student and the minimum of loss by repetition. Not that repetition is not in itself of high value; next to wandering from one university center to another and gaining a broad and discriminating understanding of a subject by observing how it is regarded by those in different surroundings, comes the advantage of hearing and seeing how the different teachers in one center regard the same subject or portion of a subject common to all of them; but with the four years' course, and the terrible difficulty,

may, the impossibility of compressing everything into it, repetition has to be reduced to the smallest limits.

And as for the man, the fuller the acquaintance with the methods of the great masters in any subject, the stronger the conviction that successful teaching depends not upon the fulfilment of any one code of procedure, but upon the peculiar gifts of the teacher. In pathology, for example, one man may be but an indifferent didactic lecturer, may, through his lectures give to his students but a poor and lifeless insight into his subject, yet in the laboratory he may be an enthusiast, and his keen interest in the disclosures afforded by the microscope or in the details and results of experimental investigation may be infectious and may fully accomplish the great aim, that, namely, of imbuing the student with an appreciation, nay a love, for the subject taught. Another may reach the same goal by his enthusiasm in the postmortem room, his deep knowledge of gross anatomical disturbances, his power of fixing in the mind vivid pictures of the results of different morbid processes. To yet another may belong the gift of clear, forcible exposition and of stimulating thought, so that the student carries away from the lectures not so much a wealth of facts as a knowledge of underlying principles and an added power of orderly reasoning over the problems which will confront him in the practice of his profession. To different men different talents, and if among these there be, for the teacher, the first great talent, that of communicating the sacred fire of enthusiasm, it matters but little what methods be employed. After all, what the university professor can accomplish is to instil only the beginning of knowledge into the student; this instilled, and a right interest aroused, it is for the student to increase that knowledge and he, with interest properly aroused, will surely "arrive."

Herein, very possibly, I speak as a heretic. In common with the majority of those having an English university training, the study of pedagogics has not formed part of my education; it is but right that in venturing to discuss "teaching" I should openly announce this fact, that my words be received with due caution. Nevertheless, if I may venture to criticise pedagogical methods, I would urge that those methods in the main are calculated for the nonenthusiastic and for the development of substitution products. They are methods whereby those cold and incapable of communicating the fire are enabled to excite the attention of the student. It is true that employing them the interested teacher may become more interesting. But first and foremost must stand ardent and evident love for one's subject, and this—like the broader love, charity—covereth a multitude of sins.

I dwell upon this matter of diverse talents because at the present moment there is a movement, initiated at Harvard, to make the teaching of pathology almost entirely practical—and it is not unlikely that this movement may develop into a fashion, and fashions, I need scarce say, are apt to be extreme, applied without thought of propriety. If I understand aright, the orderly course of didactic lectures is practically abandoned; short talks are given daily upon the main subjects of, or arising out of, the demonstrations and experiments. But it is impossible to cover the whole ground of pathology by experimental work; certain important divisions do not lend themselves to classwork in the laboratory and, even if they did, it is here in very truth a case of "ars longa": time imperatively forbids that the whole, of general pathology alone, be covered in this

manner. As a consequence the student gains a peculiar insight into certain portions of the subject and none into others, completes his course and goes out into the world with an imperfect perspective or "Uebersicht." He has specialized too soon, and is liable to be one-sided.

This is the main objection to the method. Yet it is supported (*pace* Professor Bowditch) by a long array of pedagogical arguments, and in the case of individual teachers of strong personality it may be eminently successful in arousing a keen appreciation for pathology. I will go further and say that, where good teachers are wanting, the method is calculated, by the inherent interest of the subject, to make the student appreciate and gain benefit from pathology; for by it he is brought into the inner chamber. To "see the wheels go round" in itself attracts and fascinates the beginner; to study the works themselves and find out why they go round is of the highest value. Not for a moment do I question the value of laboratory methods; I do but question whether the reaction in favor of practical teaching may not be carried too far, and whether, generally adopted, the Harvard method will be as fraught with good results elsewhere as it may very possibly be at the place of origin.

Everything depends upon the teacher in the first place, upon his opportunities in the second; and this being the case, I shall not venture to set out any ideal course. The most that can usefully be done is to discuss the place of pathology in the scheme of medical education, and, taking the different portions of the ordinary course in our subject, to consider certain aspects of the teaching of the same.

Pathology is the science dealing with the modifications undergone by the functions of the body in disease, with the causes, the course, and the results of those modifications. In order to understand deviation of function with the associated alteration in structure, it is essential to have a knowledge of normal function and normal structure; hence, the teaching of physiology and of anatomy (with histology) must precede the teaching of pathology. And here, if for a moment, I may digress into rank heresy, may I, as a pathologist, protest against the attitude of many physiologists of the present generation—an attitude which is damaging their influence in medicine. I refer to their tendency to teach their subject *per se*, regarding their science alone and regardless of the fact that their course to medical students is an integral portion—or should be—of one great whole. It is quite right that in instructing would-be physiologists this attitude be taken, and that research also, apart from teaching, be determined by the purest scientific considerations; but where in lecture and in the laboratory they have the choice of dwelling upon several branches of their subject, of equal value from an educational point of view, then dealing with medical students, they assuredly should give especial attention to such as are of especial value to those students, as forming a basis for their later studies.¹ The laws governing muscular irritability undoubtedly throw great light upon the irritability of cells in general, and nerve-muscle experiments in the laboratory, performed by the students themselves, are of peculiar value as an introduction to

¹ I do not for a moment wish to suggest that the course in physiology should be in "medical physiology" alone. The student should be given a broad grasp of the whole subject. The ideal curriculum for the medical student, as Sir Michael Foster points out to me, is an elementary course in which the outlines of every department of physiology are treated followed by an advanced course in which those portions which have a peculiar bearing upon medical problems of present interest are studied in fuller detail.

the methods of exact investigation of bodily processes; but surely it shows a lack of sense of the fitness of things to devote one-third or so of the whole course in elementary physiology for medical students to the study of muscle-phenomena alone. As a consequence, the time of the pathologist is too often taken up in teaching elementary physiology. This ought not to be.

But while complaining thus, let me urge that the physiological laboratory is peculiarly the training-ground of the pathologist. Every physiological experiment is at the same time an experiment in pathology. Each time that the physiologist varies one or other factor concerned in a vital process, in order to determine the part played by it, he introduces a deviation from the normal; the experiment is physiological or pathological solely according to the point of view of the investigator. It is in the physiological laboratory that the student should learn the methods of pathological investigation.

Thus much with regard to the relationship of the subject to the first part of the curriculum. Now as to its relationship to the latter portion.

In order to understand the significance of the symptoms of an individual case of disease and the connection between them, it is essential to have a ground-work of knowledge of how those symptoms are in general produced, what disturbances they indicate in the structure and functions of one or other organ, and how those disturbances are likely to affect the system in general. It follows that the teaching of pathology should either precede that in medicine and surgery [more exactly, in medical and surgical diagnosis and prognosis]; or, as this is commonly not possible, that the main teaching in pathology be given coincidentally with the first year's teaching in medicine and surgery, the instruction in the latter subjects being at the same time made largely pathological—that is to say, bearing not only on the symptoms of disease in themselves, but also, and particularly, upon their significance. From every point of view the latter is the better course. The student who has studied, it may be, a mere half a dozen cases of disease, realizes thereby the practical bearing of pathology; there is the same difference between the alternatives as between learning a foreign tongue at home and learning it among the people who speak it.

In his teaching, the duty of the pathologist connected with a school of medicine is emphatically to keep ever before him the idea that his course is part of the curriculum, and—though this is not a popular statement—that he is the connecting link between the physiologist and the anatomist on the one hand and the physician and surgeon on the other. His duty is so to instruct those under him that they gain a basal knowledge of the deviations from the normal, of the principles of disease, a general knowledge which can be applied for the understanding of individual cases in the wards and in practice.

Keeping this in mind we obtain a standpoint for determining the nature of the instruction to be given in the different courses forming the curriculum in pathology.

Didactic Lectures.—If the textbooks of pathology most popular in English-speaking countries are in any way to be taken as an index of the general didactic teaching of our subject, then such teaching would seem erroneous in principle. Pathology does not stand towards medicine and surgery in the Hudibrastic relationship of hector to oratory and composition. It is not primarily, as those textbooks would appear to indicate, the science

of naming one's tools. Science to be complete science does not consist in the mere accumulation of details, in the grouping of facts and the naming of the same. This much is true, that in the evolution of every science there are three stages which may overlap but are still recognizable: The first, that of vague generalizations from inadequate data, terminating in the generalizations being tested and found wanting; the second, reactive, of recognition of the urgent need for the accumulation of masses of facts, the stage, if I may so express it, of appreciation of facts as facts; and the third, the stage of full development, when with abundant data before them the workers in the science may proceed so to group those data that general laws can be recognized and theories confirmed or disproved.

Under the dominant influence of Germany, owing to the inherent love of the German student for exact detail *quā* detail, but over and above all, owing to the, in most respects, wisely conservative influence of Virchow and his school, pathology has for long years been restrained in the second stage, which many still regard as the complete science. Our textbooks, which are either translations from the German or of necessity reflect German teaching, dwell far more upon facts than upon their relationship and significance. Lectures along these lines are largely useless, save as a means of introducing the student to the whole array of morbid phenomena, and to this is owing the small influence exerted by pathology upon the medical student in the days of pure didactic teaching. But lectures can be of inestimable use if the hours be employed in applying the facts, in discussing their causation and relationship and deducing the laws governing the development of morbid phenomena, thus incidentally training the student in the methods of medical thought. If by this means the student is helped to think (and he has too little stimulus to develop the faculty during his medical course) it is comparatively a matter of small moment if some one or other conclusion or theory of the lecturer fails to stand later criticism. It is along these lines that the didactic lecture must be laid down if it is to aid the student in the study of cases of disease. If from conscientious objections, or a natural unwillingness to venture upon conclusions, the teacher cannot thus teach, those lectures are better deleted from the calendar.

Lectures or Conferences upon the Special Pathology of the Different Systems.—These should follow the course in "general" pathology, preferably during the next year; their extent depending upon the extent to which the pathology of the different systems is treated by the lecturers in medical subjects; and, I may add, as regards certain portions of surgical pathology, by the surgeons. Where, as is most often the case nowadays, special pathology forms an important portion of medical teaching, the teaching of this branch in the pathological department best takes the form of a series of weekly conferences over museum specimens, the different systems being reviewed in succession, oral examinations being held upon the gross anatomical conditions characterizing the various departures from the normal, the teacher from time to time stopping to dilate upon special topics and to systematize the facts brought forward. I do not say that this is at all adequate treatment; it is in many cases the most practicable. The true special pathology is the application of the laws of general pathology to special cases and its converse, the study of how the special case conforms to the general laws. And from the point of view of medical educa-

tion the advantage would be great were this method of regarding special pathology to govern the later teaching of our subject more than it does at present—the physician and the surgeon (as is now the case) employing the former mode of dealing with the subject, the pathologist the latter, the student thus being instructed to gain a fuller appreciation of values by regarding phenomena from two aspects.²

Surgical Pathology.—Surgical pathology, by-the-by, is an *olla podrida* of select portions of general and systemic pathology, which should be treated didactically and practically in their proper places in the pathological curriculum. It only deserves to be recognized as a distinct entity when the needs of the surgical teachers demand that these select portions be treated at an earlier period than is possible in the orderly scheme of instruction. As a course it is possibly of service as a means of giving prominence to those matters in which the views of the surgeon run counter to the generally accepted teaching of medical science or the teaching of the individual pathologist—but such divergences, after all, can equally well be noted in the general courses in surgery and pathology. Happily, with the advance of surgery—and of the surgeon—into every organ of the body, surgical pathology promises soon to be concurrent with and to fuse with pathology proper. But much can be said in favor of the establishment of a special course of surgical clinical microscopy, in immediate connection with the wards and operating theater, for the determination of pathogenetic microbes and instruction in the rapid preparation and diagnosis of sections of removed tissues.

Laboratory Courses.—The value of laboratory training is so great that much might be said upon this topic alone, but at the same time it is nowadays so fully appreciated that my remarks need be few. As I have already stated, I doubt whether with the time at our disposal we are justified in giving the ordinary student a training in experimental research; that training he should have already received in the physiological laboratory, and, having received it, it is sufficient to presuppose a knowledge of modes of investigation and to deal in the main with the practical results of disease. An occasional demonstration bearing upon the mode of development of some particular morbid condition is, however, useful. The main course must be, and must remain, that in morbid histology. For this to be truly serviceable to the student, even if it be materially aided by the projecting of sections or microphotographs upon the screen, there must be an abundant supply of demonstrators—one to every ten students—to advise, instruct, and superintend the notebooks and drawings of the same.

I can but refer, in passing, to two other practical courses, that in clinical microscopy at the hospital or hospitals, in immediate connection with the ward cases, and that in pathological chemistry. The former, while conducted in connection with the medical department, should equally be under the supervision of the pathologist; it is so valuable a portion of the practical teaching. To give practical advice concerning the latter is difficult, owing to the lack in English-speaking countries of those devoting themselves to this branch of the subject. But, certainly, the chemist who is not a med-

ical man, and what is more, a trained "biologist," is not the right man to undertake the teaching of this subject, or, otherwise, it cannot in general be recommended that such teaching be conducted in the chemical department. Pathological chemistry gives so much promise of throwing, in the very near future, so much light upon pathology in general, that the time has come for greater activity in the teaching of this branch in immediate connection with the pathological department.

Postmortem-Room Teaching.—This is capable of being made a far more vital portion of the course in pathology than it usually is. The mere instruction in methods is after all of very secondary importance, and it cannot be said that the weekly demonstration of material from autopsies, crushed, discolored, and removed from its relationships, is particularly satisfactory. But if the students, in batches, be made to attend the actual performance, and take an active part in the same, the case is very different—and more, if, after the method pursued by my colleague, Wyatt Johnston, such students be given each an organ, be made to describe its appearance, to make or study sections from the same, to study the descriptions given by standard authorities kept for this particular purpose in the adjoining laboratory, and noting the descriptions to write a diagnosis stating how far the appearances correspond to or depart from the described state, then the postmortem-room becomes the first of all laboratories, the instruction there received the most valuable, whether from the point of view of pure pathology, or of the development of the good physician.

There are many details which might with advantage be taken up and discussed—among these, especially, the relationship of the bacteriologic and pathologic courses. Personally I am strongly of opinion that in a medical school the teaching of bacteriology should be under the direct control of the pathological department, for there is no study which at the present time throws more light upon the causation and development of disease, none so powerfully contributing to the advance of pathologic science. The relative stagnation of those schools of pathology from which, in Germany, bacteriology has been divorced, is in itself an object-lesson. I cannot, however, enter into the pros and cons of the matter. Space forbids. It will, I trust, be held sufficient if here upon the broadest lines I have outlined the individual opinions of an individual teacher upon the teaching of his subject.

METHODS OF TEACHING HYGIENE.

By VICTOR C. VAUGHAN, M.D.,

of Ann Arbor, Mich.

Professor of Hygiene in the University of Michigan; late Major and Division Surgeon, U. S. V.

IN order that this theme may be intelligently discussed it may be well, first of all, to come to an understanding of the meaning to be attached to the word hygiene, and, furthermore, there will be less likelihood of confusion if we decide to whom this subject is to be taught and what knowledge of collateral branches the student seeking information is supposed to have had. Within recent years hygiene has frequently been confounded with bacteriology. It must be admitted that the latter has contributed richly to the former, but the two are by no means identical. By way of introduction I will, therefore, give a definition of hygiene as I understand it, and as I have attempted to teach it.

² An admirable method of teaching "special" pathology has, I learn from Dr. Polk, been initiated at the Corneil Medical School. Arrangements are made whereby each special course in ophthalmology, laryngology, neurology, etc., is made complete in itself, by the pathologist giving a short course on the physiology, the pathologist upon the pathology, the specialist upon the medicine and surgery of the subject. In this way the fullest results are obtained with the least repetition and overlapping, or neglect.

Medicine, in its broadest and best meaning, as a science, consists of those facts, learned by man by observation and experimentation, which can be utilized in the preservation of health or in the cure of disease—restoration to health. As thus defined, medicine is both preventive and curative. Those facts that are of service in the preservation of health constitute the science of hygiene, while those that are employed in the restoration of health make up the science of medicine in its restricted sense. Since health is a relative and not a sharply defined state of being, the science of hygiene may embrace a discussion of all conditions that affect for good or ill the physical man. It follows that the subject is a boundless one and that no man can hope to teach it exhaustively. The best that the teacher of this subject can do is to select those lines of instruction that are likely to prove of most value to his students. It is probable that no two instructors would agree in detail concerning the topics of greatest importance. For the ensuing year my schedule of lectures in hygiene will be substantially as follows:

1. PERSONAL HYGIENE.

- a. Foods.*—Definition of a food; food principles; the nutritive value of food; the economical values; discussion of different foods; the preservation of foods; food-poisoning; food adulteration; food suitable for different climates; dietaries for invalids; cooking; beverages and condiments.
- b. Clothing.*—Fibers employed and their properties; importance of texture; importance of color; selection of clothing for different climates and seasons; so-called dress reforms.
- c. Baths.*—Bathing for cleanliness; bathing for pleasure; resuscitation of the drowned; medicinal baths.
- d. Exercise.*—The necessity for exercise; pulmonary and muscular respiration. Out-door exercise: walking, riding, rowing, wheeling, games, etc. Indoor exercise: at home, in gymnasium.

2. HYGIENE OF THE HOME.

- a. The house.*—Selection of site; construction of house; arrangement of rooms; heating and ventilation; furnishings.

3. SCHOOL HYGIENE.

- a. The school house.*—Site, construction, heating, ventilation, lighting, desks, blackboards, playgrounds.
- b. Mental hygiene.*—The physical basis of education; system in study; hours for study; conditions necessary for study; rest and recreation.

4. MUNICIPAL HYGIENE.

- a. Water-supply.*—Sources; chemical and bacteriologic examination; purification.
- b. Sewage disposal.*—Systems; plumbing; pollution of streams; sewage farms; sewage purification.
- c. Garbage disposal.*—Street cleaning; by burning; by dumping into water.
- d. Tenement houses.*—Construction; overcrowding; isolation when infectious diseases appear.
- e. The sanitation of municipal and other hospitals.*
- f. Municipal laboratories.*—Bacteriologic examinations; chemical and microscopic analysis.
- g. Municipal boards of health and health officers.*—Duties; notification of infectious diseases; placarding infecting houses; disinfection; vaccination; food inspection; abatement of nuisances.

5. RURAL HYGIENE.

- a. The drainage of wet lands.*
- b. The farmhouse and its surroundings.*

6. STATE HYGIENE.

- a. State boards of health.*
- b. State laboratories of hygiene.*

- c. State quarantine.*
- d. Interstate notification of infectious diseases.*

7. NATIONAL HYGIENE.

- a. Inspection of immigrants.*
- b. Quarantine and disinfection.*
- c. The public health duties of the Marine Hospital Service.*

8. INDUSTRIAL HYGIENE.

- a. Prevention of the diseases and accidents incident to occupation.*

9. THE HYGIENE OF TRANSPORTATION.

- a. The heating, ventilation, and disinfection of railroad cars.*
- b. The sanitary care of street cars, cabs, etc.*
- c. The sanitation of boats.*

10. MILITARY HYGIENE.

- a. Examination of recruits.*
- b. Sanitation of camps.*
- c. The soldier's clothing.*
- d. The soldier's ration.*
- e. The sanitation of army hospitals.*
- f. The duties of medical officers.*

11. THE INFLUENCE OF CLIMATE ON HEALTH.

- a. The geographical distribution of disease.*
- b. Diseases of tropical countries and their prevention.*
- c. The agency of insects in the transmission of disease.*
- d. Climate and consumption.*

12. THE PUBLIC HEALTH DUTIES OF THE PHYSICIAN.

- a. The disinfection of his own clothing and person.*
- b. The notification of infectious diseases.*
- c. Isolation and disinfection.*
- d. Sanitary advice.*

I have now given a definition of hygiene and an outline of special topics that may constitute a course in this science. Before the student enters upon the study of hygiene he should have completed thorough courses in the general and fundamental facts of physics, chemistry (both inorganic and organic), anatomy, physiology, and bacteriology. It is useless to attempt to discuss scientifically heating and ventilation before those who know nothing of the physics of heat or the diffusion of gases. It would be equally idle to talk of the force value of foods to those who have never heard of the conservation of energy. If the student in your class in hygiene is ignorant of organic chemistry, the statement that the chief food-principles are proteids, carbohydrates and fats will not convey to him much information. One must know something of bacteriology before he can listen with profit to a lecture on food-poisoning.

What methods are best suited for giving instruction on the above-mentioned subjects in hygiene? To a teacher of experience it is well known that no cast-iron methods of instruction in any branch of science can be followed. The successful teacher is one who is resourceful, quick to see whether or not students are getting the information which he is attempting to impart, and ready to adapt his methods to the particular students under his charge at the time. Moreover, he must manage to give some students in his class more work than others have. In teaching hygiene this is very easily done and is generally appreciated by those upon whom the extra work is imposed, because it implies a compliment. Textbook instruction, as this is generally understood, is impracticable for several reasons. In the first place, the compass of the instruction to be given is too great to be covered by any textbook. Secondly, advances in this science are being made so rapidly that a textbook in hygiene is hardly dry from the press before it is obsolete

in some part. Thirdly, each year brings with it some new problem that must be discussed.

Who dreamed three years ago that questions in military hygiene would be of the great importance to us that they have since assumed, or who supposed at that time that tropical diseases and their prevention would so soon become matters of practical interest to us? Three years ago the bubonic plague was barely mentioned with reference to the history of epidemics and with the statement that it had recently reappeared in China and India. Now the measures adopted by our Government and European countries to prevent the diffusion of this disease are of interest to every intelligent citizen. In discussing the question of water-supply before our next classes, we cannot omit reference to the work recently done by Fuller at Cincinnati in the preliminary experiments on the purification of the water of the Ohio river, to the filtration-plant now being constructed by Hazen at Albany, or to the effects of the drainage canal on the water of the Illinois and Mississippi rivers, even if we fail to mention the valuable experiments made a few years ago by the Massachusetts Board of Health on the purification of sewage by filtration. The problems of hygiene are living questions of today and are not suitable for embalment in textbooks. Even the elaborate handbooks of hygiene that have been written—and there are some most excellent ones—cannot be placed in the hands of the student without the caution that the statements therein made represent the best information of the writer at the time of writing and not that of the present time. Again, books on hygiene by foreign authors, however eminent they may be, are not suited to American students. As an illustration of this I may mention the most admirable work by the late Dr. Parkes of England. Even in the most recently revised edition, this classical work cannot be used as a textbook in our schools. If our school-houses were not provided with more efficient means of ventilation than that recommended by some European authorities on hygiene we would expect our children to die of asphyxia, or if we were limited to the amount of water-supply per capita recognized as ample by the same authorities we would always be both thirsty and dirty. For these and other reasons, textbook instruction in hygiene for medical students I believe to be wholly impracticable.

The course in hygiene should consist of (1) lectures, (2) collateral reading directed by the teacher, (3) the observation and description of sanitary appliances, and (4) laboratory experimentation. The lectures must of necessity be condensed and should consist, for the most part at least, of the statement of bare facts. This part of the instruction is for every member of the class and it may be all that many of them can carry along with other work. Frequent quizzes should be given in order to ascertain whether or not the students correctly comprehend, retain, and correlate the statements made in the lectures. An occasional written examination on the lectures is desirable. In directing the collateral reading the teacher has the opportunity of distributing the burdens imposed on individual students as he chooses. He may request one or more students to read an article or a book and present to the class a digest or abstract of what he has read. I frequently ask five students to read one article or book and require four of them to write digests of what they have read and these are turned over to the fifth student who reads each, adds such comments as he deems fit and then hands them to

me or my assistants. (I must admit that this is by no means a pleasant occupation to read students' essays, but I am confident that since the writing of theses has been abolished, medical students have too little instruction in the art of essay writing.) Sometimes I request five students to read up some subject and then have one of them give a short talk on it, while the others are permitted to criticize.

Many useful lessons may be imparted by asking students to observe and describe sanitary works. One is asked to visit a part of the city where the sewer system is being extended and to write a description of what he sees with such comments as he desires to make. Another is asked to investigate the heating and ventilation of some public building, while a third interests himself in the plumbing. One lives in a city where the water-supply is filtered and he is asked to describe the process to the class. While there is no attempt to make sanitary engineers out of medical students, studies and observations along the lines here suggested are both interesting and profitable.

Laboratory methods of teaching hygiene do not differ from those followed in physical, chemical, and bacteriological experimentation. Practically the only hygienic laboratory courses given to medical students are: (1) The sanitary (chemical and bacteriological) examination of drinking-water; (2) The analysis of foods and the detection of adulterations. In all of the best equipped schools facilities for the prosecution of research in the various lines of hygienic study are now at the service of advanced students.

THE TEACHING OF ANATOMY.

By WILLIAM KELLER, F.R.C.S. Ed.,
of Galveston, Texas.

Professor of Anatomy, Medical Department, University of Texas; Late Lecturer on Anatomy, Edinburgh Medical School.

IN approaching the subject of the teaching of anatomy it may be well for us first to consider just what sort of knowledge of the human body we wish to impart to the medical student, and how much of the big subject he ought to know in order that he may be well fitted for his lifework; for the subject is a very large one, too large to be fully mastered in the ordinary four-year medical course, and it may be approached by the student in various ways, each best fitted to impress on him a special aspect of anatomical science. Clearly we must bear in mind that the medical student is in training to become a physician and surgeon, not a comparative anatomist, and however interesting the science of human anatomy may be in its comparative relations, it would be wrong in a teacher of medical students to waste their limited time and overstrained faculties in making them acquire a knowledge of facts bearing on the science in its biological aspects, except in so far as these throw light on anomalies and disease. The teacher himself, then, should be a physician and surgeon, or perhaps I should say, considering the limited possibilities of human energy, should be a surgeon, with a previous wide experience as a physician before his work became specialized, and he should never lose sight of the fact that he is teaching men who are placed under his care that they may become efficient physicians and surgeons. To the medical eye the whole body should be transparent, its minutest relations and connections as clear as those of a watch to the eye of the watchmaker.

those of an electric power-house to the skilled electrical engineer. To the medical touch each bony prominence, each muscular elevation, each solid resistance or yielding depression should be perfectly familiar. The physician should have eyes in his fingers and more than eyes, his whole brain should be capable of concentration in them, and the first training of eyes and fingers is given in the dissecting room. Here, too, knife, forceps, saw, and chisel are first put into the student's hands, and he must learn to use them rightly from the beginning. Surely the proper teaching of anatomy is no light undertaking, the branch no minor one in medical education. Anatomy has long been recognized as essentially a laboratory subject. From the first the student must be taught that he can learn nothing from books alone. His eyes and fingers must be taught, and so the mere enumeration of the muscles attached to a bone is useless; he must know the bone by sight and touch and should be able to mark with accuracy muscles and ligamentous attachments in chalk with his eyes shut. Every bone should be so familiar that he should be able to tell its side (right or left) and outline its prominences by touch alone. So, then, he must have such training that he will refuse to read a line without the bone before him, that he may verify the textbook description on the specimen; and he must learn to read his bones with chalk in hand, marking each muscular attachment on the bone by aid of text and diagram till no ridge or smooth surface, no eminence or depression is without its meaning. But it is in the living man that the physician has to interpret bony landmarks, and so no anatomical training is complete without a course of living anatomy, clearly a course in all its aspects best fitted to form the climax of anatomical teaching.

Skin and fasciae should be familiar as they differ in different situations, and especially the relations of the fascia lata. These are parts easily neglected; the student is anxious to get to deeper structures, and it requires a special effort to make him study the floor of the axilla, the saphenous opening, the palmar fascia and tendon sheaths, the annular ligaments and intermuscular septa. What shall we teach him of the muscles? Origins and insertions, nerve-supply and actions go without saying, and the only knowledge worth having is accurate knowledge; their grouping, too, is all-important, the great compartments in which they lie. While their relations and blood-supply must be familiar, I have always thought that it was hardly necessary that the student should spend much time in reading these, as his practical acquaintance with the muscle and his careful study of vascular relations impart to him from other aspects the necessary familiarity with these points, and neither in written nor oral examinations have I ever asked a specific statement of the arterial supply or immediate muscular relations of any individual muscle. And here I would ask "just how should a doctor know his muscles?" (Permit me to use the word "doctor" as the most convenient expression for that most important member of the whole fraternity, the specialist without a specialty, the curator of the health of the people, the general practitioner: specialists do not compare with him for a moment in his vast importance to the community.) I require the student to point the muscle out to me on the dissected body, to show me on the living subject or undissected cadaver what prominence is formed by it, to tell what part is fleshy, what tendinous, the direction of the fibers and

their general arrangement, and to show accurately on the skeleton or dissection its bony and fascial attachments. He should know what nerve supplies it; he should know that by reference to his textbook he can tell pretty accurately what spinal nerve root contributes its particular nerve filaments (it seems to me useless and nearly impossible to memorize this last fact). He should know where the nerve enters it, how thick the muscle is, and what lies under it. He should be able to demonstrate on his own person what he does with his deltoid muscle, its anterior, middle, and posterior fibers, the whole muscle acting at once; and how the arm would hang if it were paralyzed. And so of the other muscles.

Passing now to the vessels (we will take the heart with the viscera), how much should the doctor know about the arteries? I doubt if there be any fact concerning any artery in the body that he can forget without sacrificing to some extent his strength as physician or surgeon. How the vessel begins and how it ends, its relations, depth from the surface, branches, their distribution and anastomoses. There is one tendency I wish here to protest against most strongly. It is convenient for the student that he may be able to see at a glance a list of the relations of a vessel represented by a circle in the center of the page and a list of names around it, in front, behind, on the inner and outer sides; but that must be used only to refresh a well-instructed memory. That such a list should be the only method of enumerating relations is no credit to any modern textbook. The anatomist must not only know that the median nerve bears a triple relation to the brachial artery, but he must know just what relation it bears to the vessel in any particular part of the vessel's course; he must know what to expect surrounding the vessel in its upper, middle, or lower third, and I never yet met the medical student who could acquire that kind of information from a list of relations and a diagram. As to anastomoses, no one can doubt their importance, yet I do not think it necessary or wise to require students to memorize them; if they know their vessels well enough by dissection and are familiar with the course of each, it will be comparatively easy to think out anastomoses. They, like all other facts in anatomy, should be seen, learned by careful dissection, and then they will not be difficult to remember.

The veins are not such a big subject. It is necessary to know where companion veins become single trunks, and the relation of each of these to its artery; especially is it necessary to appreciate the size of these great trunks as compared with the corresponding arteries, and this is better seen in sections than by dissection. The main superficial veins of both extremities, the great subcutaneous venous anastomoses of the trunk, the anterior and external jugular veins of the neck and their connections, the venous sinuses of the dura can scarcely be surpassed in surgical importance; the hemorrhoidal, vesical, portal, and azygos systems must be familiar.

It seems to me we are apt to slight the lymphatics. Lymphatic vessels are not easily demonstrated, and in ordinary subjects the glands are usually so small that the dissector readily removes them with the fat without recognition; yet even glands the size of pinheads may become so important when diseased that no anatomical structure should be more familiar to the doctor. A subject with generally enlarged glands should be hailed as a godsend and made a permanent preparation of. I have a series of plaster casts of one which are invaluable to me. No mere words could sufficiently emphasize

the relations of the deep glands of the neck to the internal jugular; and while under ordinary circumstances it is difficult to demonstrate the iliac glands, my casts show a pelvis whose subperitoneal tissue is crowded with them in great masses. Those casts teach more anatomy than an hour's talking. I am glad to say that in cadavers prepared for dissection by my formalin method lymphatic glands and even vessels come out with unusual prominence.

As to how much of the brain and spinal cord should be taught to the medical student my opinion has changed considerably in late years. In my enthusiasm over my own freshly acquired knowledge of the central nervous system I was at one time guilty of loading my students with minutiae of doubtful establishment, and unknown physiologic import; but lately I have felt that there is so much of the nervous system that the physician and surgeon must know that these facts should be taught and taught thoroughly, while the ordinary medical student can very well afford to leave unstudied most of what has as yet attained no physiologic or clinical significance. I have lately, therefore, been guided, in determining the amount of knowledge of the central nervous system I shall require of my students, by a consultation with my colleague in the chair of physiology, and have insisted on their knowing and knowing well just so much anatomy as should fit them for his physiologic course. In the nervous system especially our terminology must be clinical as well as anatomical, and however much we may favor newer names we must duplicate our names sufficiently to fit our students to read the general run of textbooks on nervous diseases.

Of the peripheral nervous system I have vainly tried to find anything that may be safely left out. The facts as to the deep origin of the cranial nerves may be put broadly and, being mostly impossible to demonstrate by ordinary dissection, may form a fitting subject for one or two lectures illustrated by drawings and lantern demonstrations of sections of the pons and medulla, but from their superficial origin on there is little that cannot be confirmed by dissection, and nothing that can be forgotten with impunity. I have not thought it profitable to make my students memorize the exact spinal origin of each peripheral nerve, or the exact relations of segments of the spinal cord to vertebral spines, believing it impossible to keep these facts in our memory for any length of time, and also that there are very few clinical emergencies where one would not have time and opportunity to refer to a textbook for the necessary information. Passing now to the viscera. Above all things a doctor should know just where and how they lie, their relation to the surface and to each other, their vascular and nervine supply, and how the abdominal viscera feel to the hand introduced into the peritoneal cavity. Nothing can be more important than the exact relations of the stomach in all its varieties of contraction and dilation, emptiness and fullness. And as no two bodies are just alike in this respect the student should be brought into personal contact with as many bodies as possible. Fortunately, cadavers prepared by the formalin method approach very near in the relations of the viscera to what obtains in the living subject. Above all things, the anatomical teaching of the viscera should lead up to clinical aspects, medical and surgical; and the relations of the viscera are of the utmost clinical importance. The student's anatomical training should at least give him a good working knowledge of the organs of special sense.

Lastly, having acquired by dissection a systematic familiarity with the whole body, he must learn it all over again from the physician's and surgeon's point of view, and this necessitates an advanced course of medical and surgical anatomy and an anatomical course on the living subject.

Having summarized how much anatomy we have to teach, let me run over shortly the methods that I have found most serviceable in teaching it. It seems to me that lectures have but a limited application in this branch of medical teaching. The main work must consist of demonstration on the cadaver to small sections of students, and of personal superintendence of the students' own dissection. A few introductory lectures will be required at the beginning of the course, a few lectures on such parts of the nervous system as can only be taught in our limited time by diagrams, such as the tracts of the spinal cord and deep origins of the cranial nerves; one or two lectures to summarize what the student has learned by dissection of the cranial nerves, sympathetic and lymphatic systems, and that is about all. All the rest I teach by demonstration of actual dissections of the cadaver made in great part by myself before small classes while I talk. The professor should be the teacher *par excellence*. All dissecting is done during the day, and I object emphatically to dissecting at night, when the student should have time for home study. I also very strongly prefer regional dissecting as opposed to the systematic method, as thus relations of parts are more carefully studied. Bodies can be preserved indefinitely in all weathers, and there is no reason for hurry. The student in his freshman year masters all the bones of the body, and dissects the arm, leg, and thorax, including the joints; sophomores dissect the head and neck, abdomen, brain, eye, and ear; and juniors have an advanced laboratory course of surgical and medical anatomy on the cadaver and living subject. This last course also includes the study of the main points of interest in fetal and infant anatomy. The freshman class is divided into two sections, the one to dissect the arm, the other the leg, each section changing subjects after Christmas. Each section starts with the bones and must know them thoroughly before commencing dissection, having to mark each muscular attachment accurately in chalk. Then comes dissection, two men being put to each part, as I find most men dissect best in couples. One reads while the other dissects, and each dissection is preceded by a demonstration of the region, on a dissection conducted mainly before the class; the classes being small enough to enable each man to see. It takes till Christmas for the complete dissection of an extremity, commencing with the bones of the part early in October. Similarly the sophomores are divided into two sections, the one assigned to the abdomen, the other to the head and neck. The brains are removed, preserved in a formalin and glycerin fluid, having been previously magnificently preserved *in situ* by my formalin method of preparing the cadaver, and form the first subject for study after the Christmas holidays, thus preparing the men for their lectures on the physiology of the nervous system later in the sophomore year. My laboratory course for third year students is a new feature with us and promises to be a great success. As an example, the student commences by mapping out on the shaved head the bony landmarks, Chiene's and Reid's methods of outlining the fissure of Rolando, the fissure of Sylvius, and middle meningeal artery. He then removes an inch-wide strip of scalp

over the fissure of Rolando; studies the layers of the scalp from a surgical standpoint, removes the bone over the entire length of the fissure and exposes the fissure. Next he exposes similarly the middle meningeal artery. In the temporal region he studies the temporal artery from the surgeon's standpoint, the layers of the scalp here, and temporal muscles, and finally removes the squamous portion of the temporal and exposes the Gasserian ganglion. In the mastoid region he exposes the mastoid, antrum, lateral sinus, cerebellum and cerebrum. And so over the whole range of the surgical anatomy of the trunk. The limbs are studied on the living subject, and by dissections and sections of the cadaver, with a special view to ligation of vessels, distribution of nerves, amputations, resections of joints, fractures and dislocations. Such is a short outline of the method which hitherto has given me the best results. Above all things students require to be taught to see everything for themselves; and anatomy is a most satisfactory subject to teach because you can show everything. I have not touched on histology and embryology. With us these are special subjects and too large to be included in this paper.

ON THE PRACTICAL CLINICAL TEACHING OF STATE MEDICINE.

By WYATT JOHNSTON, M.D.,

of Montreal,

Assistant Professor of Hygiene and Legal Medicine, McGill University.

By instruction in State medicine, I refer to that beyond what is required to qualify the average medical student for his degree, up to what is required to qualify him as a medicolegal or sanitary official. Though the term State medicine has by usage come to signify, in this country and England, merely public hygiene, it should properly include legal medicine as well, and it is in this wider sense that I employ it.

On comparing American facilities for instruction in State medicine with those existing in Europe, we find ourselves handicapped by the absence of official connection between the medical schools and the State. Professors of hygiene and legal medicine do not with us, as they do in Europe, become as such entitled to official positions which give them opportunities to study and practice the specialties which they teach; hence, except in the case of a comparatively few State universities, it is evident that our schools must select their teachers in these branches from among those persons holding State positions, or that the latter must obtain teaching positions in order to make practical teaching possible. Evidently, active cooperation between teaching bodies and State or municipal authorities is highly desirable.

The largely increased number of teachers who now occupy State positions, as compared with that of a few years ago, naturally leads one to inquire to what extent the teaching had become more practical. We find, however, that beyond a decided augmentation in the amount of laboratory work, the State medicine courses are still largely modeled on the old plan, and little or no teaching analogous to clinical instruction is given.

Professor F. W. Draper, of Harvard Medical School, who has for some years made systematic clinical instruction in legal medicine a feature of his course, is almost the only teacher who has done so. In hygiene very little has been attempted anywhere in the way of

practical instruction in sanitation, and while courses have been begun in several institutions, they have as a rule been discontinued. I would not advocate any great increase in the compulsory work in these subjects for all students, since hygiene and legal medicine are subjects in which, while every student must know the minimum, advanced work is better left optional. This rule, which applies to all specialties, has been well pointed out by Dr. F. P. Mall in a recent article in the *PHILADELPHIA MEDICAL JOURNAL*.

I thought it might be of interest to record some attempts which I have made to place instruction in State medicine on a practical clinical basis in Montreal.

1. *Legal Medicine*.—A special advanced optional course was given in this subject for students who had already fulfilled the University requirements. I had, as coroner's physician and as pathologist to the Montreal General Hospital, postmortem material making with some outside cases a total of about 300 autopsies yearly. By being officially placed in charge, through the kindness of my colleagues, of all the medicolegal cases and damage claims averaging, arising in connection with cases treated in the Montreal General Hospital, a very interesting medicolegal material was obtained which could be readily utilized for instruction. This was given in the form of demonstrations and a weekly clinic, together with a system of medicolegal case reporting by students, similar to that followed with our medical and surgical cases. In this way, each student attending the course has occasion to report a number of cases and receives a fairly thorough training in the scientific estimation of disability, based upon the methods of the German authorities, who have made the subject a special study. This training in estimating the disability after injury or deciding whether or not a disease is really due to traumatism, appears likely to be of more real service to the majority of physicians than training in criminal medicolegal work. I prepared a class syllabus giving the principal data on the subject of disability according to standard authorities, which has been published in the *Montreal Medical Journal* for April, 1900.

For training in the criminal side of medicolegal work, besides the examination of stains, etc., each student was required to do autopsies on bodies upon which typical injuries in the way of cuts, stabs, shots, and corrosive poisoning had been previously inflicted (post-mortem). The extent to which the written report, prepared in each case was accurate, clear, and to the point, showed in how far the technic was correct and the appearances accurately observed and properly interpreted. The practice was followed throughout the course of detailing two students to each case, one representing the plaintiff or State, and the other the defense. The latter was required to comment upon the report of his colleague and criticize it. (A plan which incidentally saved the instructor a good deal of labor.)

The largest amount of material available on any one class day occurred in the spring of 1899, and was as follows: (1) A case of infanticide; (2) a case of sudden death; (3) a case of attempted murder with inquiry into mental condition of accused; (4) a case of alleged rape with examination of stains; (5) a damage suit for injury to nerves of arms; (6) an accident-insurance case of fracture of the leg; (7) an employer's liability case of loss of an eye. Such a variety of material was, however, quite exceptional, and is by no means necessary.

During the course, one evening a week was set apart for a conference at the teacher's house (after a method followed by Professor Wm. Osler) at which the work of the week was discussed. I had also in my class the students of the McGill law faculty, to whom I give a short annual course of lectures. We tried the experiment at these conferences of detailing two law students, who had also usually seen the cases at the clinic, to act as prosecuting and defending attorneys. The evidence, of course, was confined mainly to the medical points, essential outside facts taken as being in evidence when necessary. The medical witnesses were then examined and cross-examined, and after the judge (a law student) had given his decision, I was enabled to make a few remarks as referee.

The study of the cases in this way appeared to be more thorough and real than when the cases were simply demonstrated, and the students appeared to digest and apply their information very well.

A set of syllabus forms for medicolegal investigation, some of which were adapted from those of Professor Lacassagne, proved an invaluable practical guide in studying and reporting cases.

The course was followed by 20 students, of whom 12 obtained certificates.

2. *Hygiene*.—The class in this subject was a post-graduate one and the standard adopted that of the English *Diploma in Public Health*. This calls for six months of practical outdoor sanitary work and six months of bacteriological and chemical laboratory work.¹ What I wish to say concerns chiefly the plan of instruction in outdoor sanitary work, which is as follows:

A practical course in sanitation was given in connection with the Montreal Health Department jointly with Dr. L. Laberge, medical officer of health for Montreal, without whose kind cooperation the work would have been impossible.

Each member of the class was given a syllabus or prepared one for himself, detailing the points to be observed in making some special sanitary inspection, for instance, of a dairy, a vaccine institute, a water-supply, a factory, etc. Each one had thus personally to study the objects most important from a sanitary standpoint, doing also any necessary laboratory work and preparing (1) a full report; (2) a summary of the objectionable features found, and (3) recommendations for improvement. The reports made during the week were discussed at the weekly conferences of the class and criticised by the members. In their spare time, the members also accompanied the inspectors and officials in the discharge of their routine duties, though this was less insisted upon. The candidates were given opportunities of clinical study at the civic infectious hospital, though this part of the work was not organized.

By the plan followed, a maximum amount of independent work is secured, with a minimum demand on the instructor's time, and the nature of the work obliges the men to study the subject thoroughly and draw their own conclusions unaided.

Another means by which we propose to utilize the opportunities for study in sanitation without too much loss of time is a series of clinics in connection with the local health board in which the various questions of interest requiring to be dealt with during the week can be discussed before the class and the reasons explained

for the course adopted. This is a departing from the stereotyped lectures with diagrams and models of drains, etc., which often form the stock in trade of the teacher in hygiene. Set demonstrations and inspections of typical sanitary objects of interest are better, but still lack variety and do not sufficiently confront the student with the actual problems which present themselves for solution.

The laboratory instruction consisted in a practical course in sanitary chemistry by Professor R. F. Ruttan, and one in sanitary bacteriology by myself. Some lectures on sanitary law were given by Mr. C. M. Holt. Some instruction in sanitary engineering had been arranged for, but we found no time to give it. This was also the case with meteorologic work.

In recording the methods I have personally followed, I have to plead guilty of ignorance as to the extent to which they may have been already used by others, never having personally had the benefit of any systematic instruction in hygiene or legal medicine. I can only say that being struck by the fact that little was apparently being done in these branches upon the well-tried lines of clinical instruction which has been found to answer so well in other subjects, I tried to adapt them to State medicine. Although no doubt others are doing this also, they are still too commonly neglected. While, as far as I can judge, the result has been decidedly encouraging, the ultimate result of the plan may be success or failure. The experience of other American teachers who have tried to establish advanced teaching in hygiene have shown that the matter is not very easy; in fact, one reason for reporting my experience now is a fear that later on I may be unwilling to do so, and may have unrecorded experiences which, if not fortunate in my hands, might still be helpful to others.²

For the benefit of those working along similar lines, I may mention that in beginning work of this kind, one must secure beforehand the cooperation of teaching, licensing, and sanitary bodies to prevent a clashing; one must be prepared to give personally any part of the whole course if necessary; and one must find before beginning some means by which those attending will derive a material advantage from it.

A cooperation of sanitarians, teachers, and legislators, effected through some central sanitary body like the American Public Health Association, might afford a valuable means of securing uniformity in the matter of qualifications and diploma. I think that a diploma should imply at least several months of instruction; for shorter courses certificates might be given.

I think it important that in connection with medical schools facilities should be provided for advanced and practical teaching in State medicine, and that the State authorities should aid in the matter. Elaborate laboratories are less needed than practical and systematic utilization of the ordinary sanitary material on the same basis as clinical teaching. I have tried to show how facilities such as exist in every city in America may be readily made use of to place the teaching of State medicine upon the basis which it occupies in Europe.

Another direction in which teaching bodies might render more assistance to the health boards is in the systematic training and certification of sanitary inspectors and the lay officials of health departments. Uni-

¹ This standard was adopted officially by McGill University and a diploma provided for, this being arranged by Dr. F. R. Ruttan, Registrar of the McGill Medical Faculty, to whose prompt action in the matter the successful issue of the course is largely due.

² Since writing the above we have completed the course and 5 candidates, 3 of whom are health officials, have earned diplomas; 8 others, including 3 health officials, have partially filled the requirements and will complete them later on.

versities proper having the teaching-staff equipment are in a better position to do this than health boards. I am at present giving a course of systematic instruction to the sanitary inspectors in connection with the Montreal Health Department at the request of Mr. H. B. Ames, chairman of the Health Committee, as a return for the opportunities afforded for teaching my own classes. The courses of the British Sanitary Institute have been selected as the best model to follow in courses of this sort. It is difficult to see what body should hold the examinations and issue certificates such as are given by the British Sanitary Institute.

We have secured informal pledges from the public authorities that a qualification in public health will be made in the near future a prerequisite to the holding of certain positions, and in the meantime they have at my suggestion adopted the plan of giving a cash bonus to such officials already in office as may secure the qualification, on the assumption that their services would thereby become more valuable.

COMPARATIVE PATHOLOGY: ITS RELATION TO BIOLOGY AND MEDICINE.¹

By THEOBALD SMITH, M.D.,

of Boston, Mass.

THE progress of medicine, like that of other departments of human inquiry, consists of retreats as well as advances. Man frequently attempts the conquest of problems from the least accessible quarter. This is true of that stage in the development of medical science when the human species was the chief object of study. Within the past two or three decades medicine has been gradually and almost unconsciously drifting toward animal pathology as the chief, if not the sole, means of clearing up the greater doubts which a broader science inevitably brings with it. We have today definitely reached this second stage, the study of the more accessible, more varied diseases of higher animals. The preparations for this step date well back, and the most conspicuous investigators in human pathology have always had a yearning toward the rich field of animal pathology. A glance through the works of Virchow will show how largely he drew upon its resources for his ideas. Another pathologist of prominence, Bollinger, was early identified with this subject, and as far back as 1875 he was led to make the following suggestive statement, which applies perhaps with still more precision to medicine a quarter of a century later:

"By competent authorities the not unjust criticism has been made that in the newer medicine, the one-sidedness of observation, as well as that of information, is steadily on the increase. It is not our task now to trace the cause of this lamentable condition. It is evident, however, that the younger generation of medical men reveal frequently certain defects in their general medical training which have led to a partial loss of the wide horizon and the comprehensive point of view. Not only comparative anatomy, physiology, and embryology, but also comparative pathology, is in a high degree adapted to operate against this undesirable state of affairs, to widen the horizon, and to protect against a complacent narrowness."²

The decisive step toward a proper valuation of the

study of animal diseases was taken with the advent of bacteriology. Both Pasteur and Koch made their appearance in medicine as students of animal infections, and since their early work bacteriology, so far as it bears upon disease processes, has been essentially comparative in its scope and method. It was, in fact, reserved for modern etiology, the offspring of bacteriology, to lift pathology permanently out of the level of a merely descriptive science, for with the entrance of a dynamic factor, a causal element under the guise of microorganisms, the experimental era definitely began. After the opening of that vast domain of parasitism, it became possible to begin an analysis and interpretation of the phenomena of infectious diseases which go to make up such a predominant part of the substance of pathology. In this new study, the microorganisms have become the keys which unlock the secrets of biology, or the liberating impulses which, in virtue of their specific energy, set the complex processes of disease in motion according to the intent of the experimental pathologist. They have begun to convert pathology into a science possessing in a large measure the power of prediction.

The current definition of comparative pathology has thus been formulated by the course of events as the study of the diseases of the higher animals, including man. The true comparative stage has, however, still to be reached. Only when our positive information of the many, chiefly infectious diseases of animal life shall have reached a certain level can comparative studies in reality begin. The comparative pathologist still finds himself in the position of the early naturalist who scoured the earth for new species, and the dictionaries for new and untried names with which to label them. His duty for the time being will be the natural history of the different diseases as the stock-in-trade of the comparative and experimental pathologist of the future. As the older naturalists provided the groundwork for the present biologic sciences, so the foundation for general pathology must be laid by a thorough exploitation of existing diseases. Such exploitation, even along the most advanced lines, will still leave us in the dark concerning many pathologic phenomena. The higher animals do not differ very much from man, and while they may manifest in their peculiar reactions toward disease a multiplicity of adaptations and modifications of vital phenomena, these latter must be pursued still further back toward simpler organizations. We shall then be in a further stage of comparative pathology, driven back, though onward, to lower forms of life. In the course of this forward as well as backward march, pathology will eventually merge with physiology, since the various phenomena of disease must be looked upon as adaptations of physiologic processes. Ultimately they may be traced to the cell as the source of all phenomena of life.

As we reflect upon this possible course, the thought comes to us—why not go to the cell at once as the surest and quickest way of analyzing the disease processes of higher animals. This seems at first thought reasonable, but a little reflection will show its insufficiency. The ovum, though containing the possibilities and latent forces which evolve from the single cell the fully developed organism, is, after all, only a cell. The older theory of preformation, which put into it the fully developed but miniature animal, disappeared with the advent of the microscope. If we wish to study muscle cells, bone, cartilage, or nerve tissue, we go to the developing or adult organism, for they do not exist in the ovum.

¹ Address delivered by invitation at the Annual Conversational Meeting of the Philadelphia Pathological Society.

² *Deutsche Zeitschrift f. Tiermedizin*, 1875, 1, p. 20.

So with the functions of animal tissues and organs. In tracing the principles governing the defenses of the body, we should find them either wholly undeveloped in the free living cell or present only in a crude form. Through the course of evolution of higher animals, the principles of immunity have slowly become specialized and greatly magnified in certain directions, and they are probably nearest perfection in the highest types.

The stimulating researches of Metschnikoff, upon the comparative pathology of inflammation, from which he originally inferred that phagocytosis is the chief defensive process of the mammalian organism, illustrate well our theme. We know today that even if the protective mechanism of the body toward foreign intruders has its origin in the intracellular digestive processes of free-living cells, this crude mechanism has been refined and specialized beyond all imagination in higher animals. We are now prepared to realize that the crude device of the roving ameba would not do for the highly differentiated, chiefly sessile cell masses of higher animals. From these considerations it becomes evident that eventually all classes of organisms may be drawn into pathologic inquiry, otherwise we may be left with gaps which neither reason nor imagination can bridge over.

This backward progress—if such naturally exclusive terms may be coupled together—toward a deeper and broader analysis of phenomena has been the route of all inductive science. Beginning with the most complex, because, perhaps, the most important subjects, man has been retreating to simpler conditions more accessible to analysis and experiment, and, with the results before him, he is continually rectifying current information which has been accumulated by equally industrious but less fortunately placed predecessors.

This apparent retreat of medicine, which I need not force upon your belief with illustrations and arguments, as it is going on under our very eyes, is associated with another movement of equal, if not greater significance, which, in one sense, is also a retreat covered by experimental and comparative medicine, but from another point of view is a triumphant advance. The rapid strides which have been made, since Koch's discovery of the peculiar action of tuberculin, in our knowledge of resistance and susceptibility to infection and of the factors which produce immunity during the course of infectious diseases, have led to the discovery of wonderfully subtle and effective substances which may influence the incidence and course of disease. I refer to the products of bacterial growth, the various toxins on the one hand, and the products of animal metabolism under the influence of bacteria, the antitoxins, bactericidal substances, and agglutinins, on the other. These discoveries have opened our eyes to the ultimate impotency of most of our efforts to obtain artificial therapeutic substances to hurry immunity and recovery, as well as to the innate power of the animal organism to develop its own therapeutic resources directed with unfailing accuracy toward the special assailants of the hour. Where such powers fail, drugs cannot create them. But the ingenuity of medical science has found substitutes not only in bacterial products, but in the kindred body of higher animals, where they are developed under duress by artificial infection. But the energy of animal life, as displayed in the antitoxic forces of the blood, cannot create energy within the sick body, but only tide over the prostration of its mechanism of defense. Here, also, we have reached a limit in modifying and suspending the decrees of nature, and as a result we find medical science retreating

not only toward lower forms for energy, but even back along the individual life of each person and to that of his ancestors. Everywhere there is a retreat to the springs and sources of life. These must be kept pure and undefiled. The view that all successful cures with specific substances are nothing but a belated immunity is one with the almost universal tendency to stop the momentum of disease as far back along the chain of causation as it is possible for us to go.

This doctrine that disease, like other natural phenomena, is the outward expression of series of interacting causes and effects accumulating energy on the way, and that this energy is counteracted with greater and greater difficulty the nearer we approach the open manifestations of disease, has led to the almost universal practice of preventing disease wherever possible. But preventive medicine is largely the offspring of bacteriology and etiology, and these in turn owe much of their prestige to the somewhat artificial study of human diseases in animals, and to the study of animal diseases themselves.

These two movements in medicine, both taking their origin in a broader conception of disease, signify that we have come to regard medical science as only a phase of the great problem of life, and that as a knowledge of the whole is necessary to a comprehension of any of its parts, medicine must lay the whole of biology under contribution. From this point of view comparative pathology is simply one of the approaches to the science of life, but one not to be confounded with the others. Just as we are made aware in times of war of the latent energies of a nation's life, so the pathologist, in studying the disturbed equilibrium of the body, called disease, finds forces in operation of which physiology had little or no cognizance. That these forces are not new, but simply the workings of a machinery belonging to the normal body and roused into activity as a means of defense, seems well established.

According to this broader conception of pathology, a disease no longer begins with malaise and a rise of temperature, or when the patient takes to his bed, but it begins whenever the series of phenomena leading to disease, however remote at first, turns toward the particular individual in question, and whoever, through his skill and ingenuity, turns that disease aside in any portion of its course, is entitled to a doctor's credit. This broader view furthermore looks upon disease as a certain inevitable factor in life which cannot be suppressed or driven out, but which it is the task of medical science to study in all its bearings, to investigate with reference to its vulnerable side, to conciliate, and eventually to utilize for the common good.

The amended definition of comparative pathology would, therefore, be the study of the phenomenon of disease for its own sake, abstracted from any immediate association with a particular subject, such as man, on the one hand, and a particular object, such as a cure, on the other. It is a biologic study of disease, or, in other words, an attempt to explain its origin, incidence, and place as a phenomenon of life and its relation to other phenomena. If this definition is to be considered as fairly representing the attitude of the advanced medical thought of to-day, it is obvious that medical science needs to come in touch with biology at as many points as possible. We have already anatomy, histology, and embryology, physiologic physics and chemistry, which are working over biologic resources for medical use. A further and important link would be the comparative

study of disease as I have defined it, for the pathologist takes the standpoint of medicine throughout. It is his task to study the abnormal in animal life, and in this respect he should stand closer to medicine than the physiologist or the morphologist. The territory covered by any branch of biologic science must be small in order to be properly cultivated. Unless there are a sufficient number of adjoining or overlapping territories extending from biology to medicine, the resources of the former will remain unknown and unused.

Let us now turn to some practical matters by means of which this broader conception of medicine may be realized. What is the true direction which education and research should take? Individual views cannot count for much to-day. Only by arousing attention and often vigorous opposition from various quarters can we hope to promote our object. Let us first of all glance at the field of operation of our subject and some of its present resources. It seems to me that at present the most fertile domain to be explored is that comprising the varied diseases of the higher animals. If I said simply infectious diseases, the program would be amply large. A thorough investigation of the latter will inform us of the limitations of infectious agents, and by the way of these limitations we shall most easily be guided to other still unknown causes of disease. In this field, which must form the groundwork of comparative pathology, much has already been accomplished, mainly with the aid of grants made by various governments in aid of agriculture. In our own country we have a central government making large, regular, and often very lavish, incidental appropriations for the study of animal diseases. We have in every State and Territory a fund donated by the national government for agriculture, a part of which may be used for the same purpose. There are also appropriations made by certain States for similar work within their own boundaries. These, all together, represent, I may safely say, the annual income of a fund as large as that possessed by many of our smaller colleges.

The utilization of this fund under governmental authority has certain advantages and disadvantages which we should keep clearly before us. If we look upon the bright side we see that much has been unearthed that would otherwise have lain dormant for years. We have within the last decade learned to accustom ourselves to the idea of the rôle of insects in disseminating certain diseases, and their *modus operandi*. We have obtained valuable data upon such mysterious diseases as foot-and-mouth disease and rinderpest. Our knowledge of tuberculosis and various animal plagues has made considerable progress, and with the aid of men devoted especially to comparative pathology, this fund of information will be worked over and moulded into use for medical science in its widest sense. Another benefit of more popular character derived from the work carried on with the public funds is the dissemination of medical knowledge on a large scale by publications free to all. A kind of school for instruction in disease is created, and as such it cannot but do good in clearing the receptive mind of that mysticism concerning disease which is the eldorado of the modern quack. The agricultural world has within its reach the information concerning infectious diseases which is the outgrowth of medical science. I may be over-estimating the value of this free literature, but I firmly believe that the doctor and the health officer will find a more tractable and reasonable community where epizootics among

valuable animals have led to reflection and serious thought, stimulated and guided by appropriate reading.

These are the chief advantages which occur to me as the outcome of such work in our own country. But they are offset by difficulties. There is, in the first place, the constant warfare between the so-called theoretic or scientific and the practical. There seems to be a continual struggle between the demand for prompt results and the abortive efforts of the government to satisfy it. The identity between scientific and practical is not sufficiently grasped by the people. The truly practical is the knowledge which ripens on the tree of science instead of the tree of empiricism, and it cannot be other than scientific. It is the unproven theory or fad upon which the public money is so frequently sacrificed. I believe the thorough testing of new theories upon animal diseases to be a legitimate function of governments in which no means should be spared. When the principle has been established, then the time has come for the inquiry—Will its application pay? As a rule the reverse is practised. The experimenter stumbles along with inadequate means, and as soon as a ray of light appears, or he thinks he sees it and so expresses himself, he is overwhelmed with funds. The theory is made to work, whether it resists or not. The scientific atmosphere is furthermore disturbed by the temptation which comes to the investigator to praise or overrate the results of his own work in order that it may be the recipient of that approbation which insures further appropriations and continued tenure of office. These difficulties are well known. Among some of the remedies to be suggested are selection of the best men, their adequate compensation and their protection in office, so that the praise or blame of inexpert laymen supporting some fad or doctrine may not disturb the modest self-critical attitude of the investigator. We should endeavor to promote the progress of investigation and the diffusion of knowledge rather than the distribution of so-called curative and diagnostic agents. These will take care of themselves. The economic as well as scientific importance of animal diseases is so great that the national government could with profit maintain a trained expert for every one of the plagues that decimate our domestic food-producing animals. It could afford to give him all the facilities for experiment and study and travel necessary to keep our knowledge of that particular disease in this and other countries up to the high-water mark of medical science.

Another means of promoting the best use of government funds in the interests of accuracy and economy—a method by no means new and in use by the other governments—is the alliance between our higher institutions and the government in such a way that the more abstruse, more fundamental work can be done by the most accredited men in different institutions. This method would not only lead to greater efficiency, but it would accrue to the benefit of medical science, in which all the people are equally interested. It is, in fact, almost necessitated by the geographic distribution of many diseases. In short, if the medical profession would begin to regard the great domain of animal diseases as its own, if it would accept the broad view of disease I have endeavored to sketch, and take a sympathetic interest in the efforts to study pathologic phenomena wherever they appear, there would be but little difficulty in utilizing to the best advantage the great resources furnished by public authority.

There are other resources for the study of comparative

pathology which I would be remiss in passing over unmentioned. In all biologic laboratories many problems under investigation either have a direct bearing upon general pathology or else are on the border-line as ordinarily drawn. We shall undoubtedly perceive in the near future a strong current setting in toward pathology from biology, which will meet the one setting in from the medical or anthropocentric side, and passing from the pathology of the higher to that of the lower animals. Of these new possibilities let the biologist himself speak.

If we next turn to our subject as a general educational factor, we shall discover, upon a little reflection, possibilities worthy of development. Starting from the doctrine I have brought to your attention, that pathology is a phase of biology, there is no reason why its principles cannot be taught in our colleges to those who intend to enter medicine, or who wish to gain a general knowledge of disease processes, inasmuch as it is now possible, with a little judicious selection, to teach pathology in the laboratory without any recourse to the hospital or its autopsy-room whatever. The great omnipresent problem of parasitism, with its numerous pathologic manifestations, may be made a biologic study as instructive and broadening as any that may be offered to those already trained in the fundamentals of biologic science. Whether we desire this innovation or not, the necessity for earlier specialization toward medicine continues to grow, and that institution will reap the benefit which adapts itself most smoothly to the changing demands. In fact, an impartial view of our educational methods and aims cannot fail to occasion surprise that while we have endowed professorships and equipped workshops (be they libraries or laboratories) in so many departments of human inquiry, from astronomy to Sanscrit, we have but very few for the study of general pathology, that subject which comes as near to us as any. What the intelligent public need is instruction in the newer ideas of cleanliness. Has not this idea undergone a complete revolution in the minds of all older physicians, and does not it undergo a change in the mind of the student as he passes from school and college into medicine? The old adage that cleanliness is next to godliness stands unshaken today, because it is a universal method of repelling the agents of disease. The pointless fastidiousness of everyday life should be converted into a pointed, useful weapon of defense in the hands of the public generally. May not our indifference to the diffusion to sound biologic knowledge concerning health and disease be in part responsible for the lamentable diffusion of charlatanism and the multiplicity of the "isms" which claim the power to cure and the right of admission to the ranks of the medical profession? Evidently the subject of disease repels the average student; but this repulsion is largely due to our ignorance of the subject of disease and its unnatural separation from biology. As an introduction of the educated laity to the facts governing disease, animal pathology would be the most wholesome as well as the most broadening study. It could be so conducted as to be free from any personal dangers, since not a few animal diseases are quite harmless to man. Finally, the influence of a wider dissemination of the facts of general pathology as disclosed by animal life would be of very great value in the formation of a healthy, alert, and receptive public opinion upon the many questions of sanitation which are of such momentous importance in our congested centers of population, and which public inertia often keeps at a standstill.

The place of my subject in purely medical instruction remains to be created. Since each department or branch of medical teaching is not the result of the best ideals, but rather moulded by the conjoint pressure of all the other branches upon it, any new branch that may claim independence and endeavor to push its way into the limited space will probably have a quite bizarre shape for a time. It would be useless, therefore, for me to suggest a definite finished program. I should, however, consider the little influence it may wield for a time to act chiefly in the direction of enlarging the student's views of disease. He needs a truer conception of the general relations of disease to other phenomena of nature, of the powerlessness of man to create energy in the sick on the one hand, and his power to husband and possibly divert it wherever needed, on the other. These facts lie at the foundation of medical science. Among the special advantages which a comparative study of disease offers are the accessibility of various types of infectious diseases and the study of these diseases from beginning to end at short range, the important conception of variation of host and microorganism, and hence of the resulting disease—in other words, the continual flux of pathologic phenomena, a fact so easily demonstrated but so often lost sight of when our attention is concentrated upon a single species. The student comes in contact with disease at once from all directions. When we bear in mind that most, if not all, good teaching is a more or less arbitrary tearing apart of related phenomena, either because some are inaccessible or for greater simplicity of presentation, the educational advantage to the student of having all his studies focussed on a single object entirely under his control is worth the temporary detour toward animal pathology.

There are many other minor advantages derived from the study of animal diseases, of which I shall delay to mention but two. The investigation of human diseases must be continued by experiment on animals wherever possible. In the study of animal diseases we can continue them upon the same species from beginning to end, and thereby avoid erroneous deductions. The study of typhoid and cholera in guineapigs is quite a different thing from its study in man. Again, we are able to study animal diseases at all stages. This is only apparently true for man. A case of typhoid fever which terminates fatally in the first week is probably due to a much more virulent bacillus or a weaker resistance than one ending fatally after the third week. The two cases are not stages of the same type of disease. In animal diseases we may terminate life at any stage for purposes of investigation, and thereby gain a better insight into the evolution of disease processes. I believe that the whole subject of the diseases of the blood would be greatly simplified by adopting a comparative standpoint and extending our studies to animal life.

In my remarks I have been mingling together thoughts bearing upon instruction and research quite indiscriminately, because their interests are to a certain extent the same. Yet they are not identical. Medicine, in our own country, has been so preoccupied with building up medical education devoted directly to the training of practising physicians that little energy has been available for advanced work in the building up of medical science itself. The need of research to keep the springs of knowledge pure is now being generally realized. In Europe institutions are appearing in which instruction is quite secondary to research, and into which students are admitted to create knowledge rather than to absorb

it. The need of such institutions in our own country is far more pressing than that of new medical schools. There is no sign on the horizon, however, that foretells their speedy coming. I wish to enter here a plea for institutes in which the large territory of animal diseases may be made accessible to research and instruction. Such an institute, besides performing work of great economic value, would fill in the gaps of the more pointed and immediately practical instruction in human pathology, and could be adapted to the comparative study of other branches of medicine. The pathologist interested in the lesions of any organ, such as the kidney, will seek light in the direction of animal pathology. The clinician will be eager to study comparative changes in the morphologic elements of the blood. He will welcome the opportunity to study the pathologic secretions of the kidney in animals. But before this can be realized there will be needed well-equipped departments in which all the accessible diseases and lesions of animal life are mapped out, studied, and classified in connection with as complete as possible a history of the animal furnishing the material. Such a department will come to represent the clearing-house through which material becomes accessible to general medicine. Though the achievements of the comparative pathologist himself may not for a time rise above those of the descriptive stage, owing to the great extent of the territory to be covered, he will be in a position to put into circulation valuable material, and his laboratory should become the center of all inquiring spirits who find their path blocked by the necessary restrictions governing the study of human diseases.

I have no doubt that the program I have outlined of comparative pathology as a factor in education and research will be regarded as fanciful, because at present not feasible. I acknowledge the anticipated criticism as being in part justified. The ultimate success of such a program will depend on a variety of factors, especially on adaptability to a greater subdivision of work now becoming necessary. Pathologic anatomy is breaking up into a number of specialties devoted to different objects. Pathology will divide along other lines of cleavage. Experimental science demands division according to methods of work. The most successful pathologic work will be done by those specially trained in morphology, physiology, and chemistry, and the best pathologic laboratory of the future will employ such specialists working together. The limited capacity of the individual mind for the absorption of details demands the shrinkage of our own individuality and its intimate cooperation with others.

Another criticism which I also anticipate is the one that pathology is already taught comparatively by the best teachers. This I gladly acknowledge to be true, and it is their influence which makes any further advance in the direction I have pointed out possible at present. Yet the point of view of the human pathologist will generally be different from that of the comparative pathologist, for the former is more directly associated with medical practice. He is in many of the smaller institutions still too much preoccupied with routine work to get much time for the working out of problems having a general bearing upon disease. Only an adequate force of assistants and an extensive material equipment will enable him to treat disease from the comparative standpoint. This would be equivalent to creating a new department. It should also be said that a department covering too much ground is apt to fall to pieces

sooner or later, because the interest of the investigator is apt to grow narrower and deeper with the passing years, and the success of the laboratory depends, as we all know, upon the personal interest of its director in all the details of the work. I see, therefore, no valid reason why an independent department of comparative pathology is not compatible with the best results. At the same time the gradual evolution of such a department may go on under the wing of human pathology until the fledgling is ready to fly to another perch.

In conclusion, I wish to call your attention to certain problems which are not, as a rule, recognized as coming within the scope of medical science, and to which biology has already given much attention. I believe that we all agree that the medical science of the future should not exhaust itself in the task of trying to save or prolong individual life, but it should endeavor to minister as well to the wants of the social body of which we are the units. Though the universal demand be to save or prolong individual life, it does not require deep thought to believe that the exercise of this function alone may not, after all, be the best that medicine can do. The pathology of individual life may be the physiology of the higher organism to which the individual belongs. Pathologic phenomena may be correctives of conditions of unstable equilibrium of the social body, whose true significance may entirely escape us. The propriety of giving attention to the more general phenomena of disease in addition to the saving of individual life and the relief of suffering, therefore, is obvious. The medical profession should, in other words, give itself up to reconstructing as well as mending the individual. This work of reconstruction, which manifests itself in the activity of personal and public hygiene, has already drifted partially out of the hands of the medical profession, partly of necessity, partly because it has been too absorbed in the process of mending. Yet the medical profession is the only one which has the resources to successfully carry on this work. In this broader field the subject of parasitism naturally falls to comparative pathology. By the word parasitism I mean all associations of organisms with animal life, be they bacteria, or protozoa, or fungi, or the larger animal parasites. Such associations should be studied, whether they produce a manifest disease or not, or whether in producing disease they are regarded as secondary or accessory agents, or of primary importance, because our hypotheses or suspicions are not sufficient to create a fact. A symbiosis in one species may be the source of a fatal disease in another or in the same species in another climate.

Parasitism, from a general point of view, is a weapon used by nature to eliminate those that fail to reach a certain standard. Parasites take the place under domestication of those larger enemies which every species has to encounter and from which the only protection is perfect working of the powers of resistance, whatever form they may assume. It is one of the problems of comparative pathology to analyze the relation between host and parasite and to find out what is to be credited to predisposition, what to the specific energy of the parasite. Such a problem includes the whole environment of the individual as well as that of his ancestry. This phenomenon of parasitism is closely linked to the evolution of society as well as to the domestication of animals. In this process of civilization or domestication pathologic conditions arise owing to imperfect adaptation to rapidly changing conditions. The task of pathology is to trace this want of adaptation, to analyze it, and to

determine its ultimate effect. The pathologic conditions may finally become physiologic in a new environment, or they may remain pathologic and lead to great destruction. I may mention as one of these problems that of tuberculosis. On the one hand, it is claimed that this disease is a result of environment with the parasitic factor of only subordinate importance; on the other, it is claimed that the parasite is chiefly to blame, and that all that is necessary is to protect ourselves against it. Much can be learned concerning these problems by a careful, continuous study of animal life under domestication. Many parasitic diseases of higher animals and plants appear in an accentuated form with domestication, and it becomes the duty of pathology to accurately estimate the separate influences which conspire to bring about this state—the parasite, the artificial environment, the relaxation of the struggle for food, and a number of others. The same problem is confronting us with the human race. This, reduced to its simplest terms, may be defined as the adaptation of the individual to so-called pathologic states, rendered inevitable by the great diversity as well as monotony of conditions under which individuals must live in forming together a higher social organism.

It is furthermore possible that the efforts which have been made by biology to apply its principles to the higher social organization may in the future be seconded by pathology. There are many traits of the social body which recall certain phenomena in animal pathology. Can the latter in cooperation with biology throw any light upon the path we are going? Undoubtedly we all recognize the fact that even prodigious erudition and great prophetic vision cannot as such be of any influence in guiding the world, but that the knowledge must be vitalized by assimilation through the units which compose it—in other words, through education. It is difficult, however, not to be optimistic in holding the belief that biology will be of great service in foreshadowing the evolution of the social organism, because the same principles appear to be at work that have brought to such perfection the cellular organization of man. I refer, of course, to the mechanism and not to the essence of life, which will remain for mortal man ever a mystery and a faith. In the evolution of life there have been ups and downs, movements forward and backward, the latter representing the disturbed equilibrium or the pathologic phase. In the progress of society we seem to note similar movements. Can individual men, by a study of the forces that tear down as well as those that build up organisms, and by the popularizing of the knowledge thus gained, so that it may become part of the mental and moral outfit of the individual, save society from impending catastrophes similar to those that have overtaken it in the past: or will it simply be the privilege of the individual to foresee the future and analyze the past? In any event, if pathology could simply, from its own material and its established principles, interpret and verify, or even reconstruct and perfect, the simple, moral rules which have served as a guide for the individual of the social organism for nearly twenty centuries, its task would not be in vain.

Plague.—The returns for the week ended July 21, show for all India only 198 deaths from plague. The fall in the death-rate from plague is annulled by the great increase in mortality in Bombay from cholera. During the week ended August 11, 29 cases of plague occurred in Hongkong, China, and 28 deaths from the disease. A fresh case of plague is reported in Sydney, Australia.

ON THE ETIOLOGY OF TROPICAL DYSENTERY.

Middleton-Goldsmith Lecture, Delivered Before the New York Pathological Society, April 12, 1900.

By SIMON FLEXNER, M.D.,

of Philadelphia, Pa.

Professor of Pathology, University of Pennsylvania.

THERE are few subjects in medicine that have attracted more attention than dysentery. Its history dates from the earliest written records and its ravages, unlike those of many of the pestilential diseases, have continued practically unaltered to the present day. The most ancient writing upon medicine—the papyrus Ebers—contains allusions to dysentery; the oldest Indian medical writers refer to it under the name "Atisar," while Herodotus speaks of its prevalence in Thessaly. Hippocrates, however, was the first to regard dysentery as an independent disease. I should hesitate to bring before this audience a subject so time-worn were it not for the fact that the nature and more especially the etiology of dysentery are among the problems that still await a satisfactory solution. Although the destructive epidemics which characterized the appearance of the disease in ancient times, and which were not unknown even as late as the last century, are in our own day encountered only as accompaniments of war and famine; nevertheless, dysentery still occurs in epidemic form in many Eastern and Western countries, while in the tropics the disease—not unlike cholera, another infectious disorder, the characteristic lesions of which are situated in the intestines—would seem to have found an endemic home.

Our imperfect knowledge of the nature of dysentery should be ascribed neither to lack of opportunity for the study of the disease nor to lack of energy in its pursuit. The literature contains some of the most distinguished names among clinicians and investigators, thanks to whose efforts its clinical history, its epidemiology, and, to a less extent, its pathological anatomy have received partial elucidation. Nor has the disease in the past quarter of a century escaped the attention of the bacteriologists, although it must be confessed that the results of somewhat extensive studies along these lines have been far less conclusive than might have been expected. Given a disease that is never entirely absent from temperate and tropical regions, that appears with epidemic severity, that permits of easy access to the *materies morbi*, one would certainly have been tempted to predict that the success achieved in so many other and apparently no less difficult fields would probably be repeated. That the attempt to establish a common etiological factor for all cases of dysentery has thus far failed, this audience need not be reminded. That this failure has tended to emphasize the existence of several pathological states, for which the term dysentery is employed merely as the collective designation, need not be maintained here. But that these conclusions regarding the disease may after all not be in keeping with the facts is at least open to suspicion. When we recall the protean nature of other infectious diseases, among the most common of which are tuberculosis and typhoid fever, there can be no *a priori* objection to the hypothesis that the causative agent of dysentery need not necessarily vary for each of the many types of the disease that have, from time to time, been distinguished.

For the purpose of my inquiry, I shall consider briefly

the clinical and pathological types, after which I shall ask your attention to the evidence for belief in specific causes. In considering this topic I shall endeavor to bring out the bearing of such studies upon dysentery in general and upon particular types of the disease. Finally, I shall hope to emphasize certain considerations connected with the etiology and pathology of dysentery by reciting some observations made upon the dysenteries prevailing in the Philippine Islands.

Types of Dysentery.—That the lines of demarcation between the several clinical and pathological types should be inaccurate is not a matter of wonder. Both the beginning and end of any given instance may vary widely, and the symptoms and lesions of cases arising sporadically in temperate climates may agree with those of dysentery occurring endemically in the tropics or epidemically in both localities. The terms "catarrhal," "tropical," "epidemic," and "diphtheritic," are far from signifying sharply-defined entities. The clinical manifestations and pathological lesions of the catarrhal variety occur in all kinds of dysentery and in all places where the disease prevails. Ever since the time of John Hunter there have been those who, upon pathological-anatomical grounds, have separated the endemic from the epidemic disease, and the line has been even more sharply drawn during the past decade, since the discovery of *Amœba coli* in its relations to tropical dysentery. But the distinction between tropical dysentery and the epidemic disease is far from being sharp and constant. Diphtheritis and ulceration are not safe criterions, for while the former is commonly present in the epidemic disease, it occurs also in the tropical malady, and may, according to Kartulis, be associated with the ulcerative amebic variety, in which the lesions begin with destruction of the submucous coat of the gut.

As must always occur when classification of a disease proceeds upon clinical and pathological rather than etiological lines, the literature of dysentery is burdened with an interminable mass of appellations indicating the nature of the disorder or the author's conception of its pathological anatomy. Dysenteries, however, are now divided by the chief writers into several groups, depending upon the clinical history or the mode of prevalence. Thus Osler writes of 4 varieties, the acute catarrhal, the tropical or amebic, the diphtheritic, and the chronic dysentery. Davidson considers the subject under 2 headings: (1) according to prevalence—epidemic, endemic, the dysentery of war and famine; (2) upon clinical grounds—acute fibrinous or pseudodiphtheritic, and chronic dysentery. Kartulis describes endemic, epidemic and sporadic varieties; Manson speaks of a catarrhal and ulcerating dysentery, while Delafield distinguishes in the environs of New York at least 5 distinct types of this disease, only one of which would appear to be due to a specific agent—*Amœba coli*.

Evidences for Specific Causes. Bacteria.—The presence of bacteria in the stools and tissues in dysentery was demonstrated by Klebs, Prior and Ziegler, whose studies, carried out upon the epidemic disease, have now only a minor historical interest, although Ziegler still holds that the relations of certain bacilli to the lesions speak for their pathogenic action. The early studies of Ilava upon the epidemic disease yielded quite inconclusive results, since, although he was able to obtain as many as 19 different kinds of bacilli in cultures, inoculations into animals failed entirely to reproduce the morbid

process. Chantemesse and Widai were somewhat more fortunate. From five cases of tropical dysentery they obtained a bacillus which, when injected into the stomach or rectum of guineapigs, give rise to diphtheritis, an observation which Grigoriev, who believed that he had isolated the same microorganism from 10 cases of dysentery, failed to confirm.

Maggiori, who studied 11 cases of the epidemic disease, obtained *B. coli communis* regularly and in large numbers. Less frequently *B. proteus vulgaris* was isolated, while in some cases the pyogenic cocci and *B. pyocyaneus* were found. This investigator considered it highly probable that the disease was caused by a *Bacillus coli* of intensified virulence—a conception also shared by Laveran, Arnaud, Celli and Fiocca and Escherich, who isolated the same organisms from dysenteric cases. Arnaud's series was larger, embracing 53 acute cases occurring in Tunis, from all of which *B. coli* was isolated. The spleen of a fatal case also yielded him the organisms. The ingestion of cultures in the case of several kinds of animals gave no results; while rectal injections of bouillon cultures, previously raised to 60–80° C., produced in two dogs a fatal and characteristic dysentery—a result in striking opposition to those reported by other writers.

The studies upon this bacillus by Celli and Fiocca are the most important which we possess. Their cases numbered 62 and included examples of the sporadic, epidemic, and tropical disease occurring in Italy and Egypt. From the fact that especial attention was paid to the occurrence and action of *Amœba coli*, the results of these authors are doubly useful. They exclude this organism as the cause of any form of the disease and consider that a variety of the colon-bacillus, of especial virulence, which they designate *B. coli dysenteriae*, is responsible for the lesions. Along with this colon-bacillus they found typhoid-like bacilli and streptococci. Their experiments upon animals are also more conclusive than any others. With cultures they were able to produce dysentery in cats, and while they admit that other microorganisms were also capable of producing similar results, they found that the latter acted far less constantly than their dysenteric bacillus. A toxin separated from growths of the organism was found to give rise to similar conditions. Celli, in another publication, expresses the view that it is this toxin that first exerts an injurious effect upon the intestinal mucosa, after which the destructive lesion is produced by the pyogenic cocci. Results similar to those of Celli were obtained by Del Pino and Alessandri. The latter, working on a case of postoperative dysentery, secured cultures of *B. coli* that yielded a toxin capable of setting up dysentery in young cats. In their most recent paper, Celli and Valenti describe the production in dogs of serums, which, when tested upon experimental animals, exert a protective and healing effect. Upon human beings its action was not equally positive.

The colon bacillus is also believed by Escherich to play an important part in the production of a contagious enteric disorder (colitis contagiosa) in children. In its morbid anatomy the disease agrees with catarrhal dysentery.

The bacilli thus far enumerated, except those of Chantemesse and Widai, so far as they could be studied in cultures, have shown no specific properties. They all represent a well-known bacterial species, constantly present normally in the situation from which the organisms were obtained in disease, and whose only unusual

properties were increased virulence when tested upon animals, and a capacity to set up enteritis when injected into the intestines of dogs and cats.

The investigation of an epidemic of dysentery which prevailed in Japan yielded different and apparently more convincing results. Ogata isolated fine bacilli, which liquefy gelatin, stain by Gram's method, and set up, when introduced by the mouth or by the rectum into guineapigs and cats, intestinal ulcerations. The organism regarded by Ogata as the cause of epidemic dysentery was isolated from 23 cases of the disease occurring in Padua by Vivaldi. Since that time it appears not to have been found again.

This list does not entirely cover the bacillary species isolated from cases of dysentery. The recent publication of Shiga, who also studied the disease prevailing in Japan, is needed to complete the number. But as this investigator's studies have a very direct bearing upon my own, I shall defer speaking of them for the present.

On the other hand, a causative role in the production of dysentery has also been ascribed to the pyogenic cocci. Besides being found in association with bacilli, by several of the investigators already mentioned, they have been regarded as the chief pathogenic agents by Zancanol, whose studies were carried out in Alexandria, by Silvestri of Turin, by Bertrand and Baucher of France, and very recently by Ascher, who investigated cases arising in Eastern and Western Prussia. These cocci, especially the streptococci, were capable in certain instances (Silvestri, Ascher) of setting up, in cats, dysentery and liver-abscess. The cocci isolated by Ascher were also said to have shown the agglutination reaction with the blood-serum of the patients from whom they were obtained. As a cause of a special variety of endemic dysentery—the endemic enterocolitis of Cochin China—Calmette obtained *Bacillus pyocyaneus*. The same microorganism was isolated from a small epidemic of the disease occurring in New York State by Lartigau, in another epidemic in children prevailing in Canada by Adami, and in certain sporadic cases of gastric and enteric infection by L. F. Barker in Baltimore.

Protozoa.—Because of the great diversity of the normal intestinal flora the varieties of bacteria which can be isolated from the dejections and intestinal contents are relatively numerous. The differences in the numbers and kinds of bacteria capable of flourishing there, rendered possible by the existence of pathological conditions, readily account for many of the results of the bacteriologic studies given. With animal microparasites the case is different. Protozoa do not exist in easily demonstrable forms or numbers in the dejecta in health, and the number of species occurring under all conditions is small. Of these the list is confined to a few kinds of flagellates, which even when present in considerable numbers do little harm, and the amebae.

It is to the role of the amebae—a particular variety of which has achieved the distinction of being connected in a causal relation with endemic dysentery—that I wish to direct your attention. Since the studies of Kartulis, Councilman and Lafleur, and Kruse and Pasquale, so firmly has the idea of this connection taken hold of the popular medical mind, that the designation "amebic" as synonymous with "endemic" or "tropical" dysentery has been widely adopted. And yet the evidence upon which this belief

is based cannot be regarded as convincing. Until we shall have gained means of differentiating amebae other than those we now possess, and, moreover, until we are able to control their development with at least as great perfection as in the case of bacteria, the question of the precise part played by them in dysentery cannot be satisfactorily determined.

Since the historical observation of Lambl upon the occurrence of amebae in the dejections of human beings, and especially since the confirmatory observations of Cunningham, Lewis and R. Koch, our knowledge of the distribution of these organisms in human beings has constantly widened and deepened. It was, moreover, the study by Lösch of a case of dysentery in which an ameba, called by him *Amœba coli*, occurred that gave the impulse to the investigation of the pathological actions of such organisms.

The importance of amebae was further enforced by the demonstration of the organisms in sections of dysenteric ulcers by R. Koch, first in Egypt and afterwards in India. Following these successes, and probably directly through the suggestion of Koch, Kartulis began his series of observations and publications, which more than any other similar writings have tended to isolate tropical dysentery and place it upon a probable etiological basis.

The work of Kartulis need not be reviewed in detail in this place. His conclusion that in every undoubted case of dysentery occurring in Egypt the amebae are present, has not been entirely confirmed. That they are, moreover, never present in the intestines in other enteric diseases and in health has also not been the experience of all other investigators. But that amebae are abundant in many cases of tropical dysentery and may also be demonstrated in the contents of the hepatic abscess in the disease, the studies of Kartulis and those of subsequent investigators have definitely shown.

To follow the list of discoveries in cases of dysentery which have accumulated in the last decade is unnecessary and would carry us too far afield. Reports confirmatory of the results of Koch and Kartulis have appeared from many European countries, the Pacific Islands, and from both North and South America. Ten years have, however, seen a modification of the views regarding amebae, as causes of pathological conditions in human beings. The demonstration of amebae, indistinguishable from *Amœba coli*, in various intestinal diseases and even in healthy persons, has necessitated a recasting of the exclusive belief in their pathogenicity and relation to dysentery.

That amebae may exist in diseases other than dysentery was conclusively proven by the early observations (Cunningham, Lewis) upon choleraic discharges. More important results were obtained by Grassi, first in 1882 and later in 1888. He describes amebae which may occur, in considerable numbers, in diseases as varied as typhoid fever, cholera, pellagra, and colitis secondary to tumors. He demonstrated their presence in diarrheas and dysenteries, but at times also found them in the dejecta of healthy individuals. That amebae may exist in the intestines without any disturbance of the health of their host was, therefore, definitely established by Grassi's observations as well as by those of Calandrucci, Massiutin. Kruse and Pasquale, Gasser and Schuberg. The observations of the last-named investigator are especially valuable, in that he showed that to the reaction of the lower colon and the consistence

of the feces was due the fact that amebae could not be constantly found with comparative ease in the dejecta. If a laxative, as for example, Carlsbad salts, is administered and the contents of the upper colon are then collected and examined, amebae are frequently demonstrable. Moreover, under these conditions flagellates—the trichomonas and cercomonas—appear in the stools. He looks upon these parasites as common commensals in man.

It can, therefore, no longer be held that amebae are necessarily pathogenic when found sojourning in the intestine in man. Indeed, the necessity of recognizing distinct species of amebae had already begun to force itself upon thoughtful students, who until lately believed in their constant pathogenic action. Quincke and Roos, who observed amebae first in a healthy individual, and later in two widely dissimilar cases of enteritis, tested the different organisms concerned for pathogenesis upon cats. From their results they believed that according to certain structural differences, and the action of the parasites in engulfing red blood-corpuscles, two main varieties or species can be distinguished, the one phagocytic for red blood-corpuscles and pathogenic for man and cats—this species being identical with *Amoeba coli* of Lösch—the other, non-pathogenic and nonphagocytic for blood-corpuscles, which they designate *A. coli mitis*. According to this view *A. coli*, *A. felis*, and *A. dysenteriae* of Councilman and Lafleur are all one species; *A. coli mitis* is a harmless saprophyte, or at least is one of relative pathogenic insignificance.

It requires no elaborate argument to bring out the fallacies of such a method of distinction. Results following the introduction of so complex a material as dejecta into an animal cannot be accepted as deciding the properties of any single constituent. What has already been said concerning the ability of pure bacterial cultures to produce enteric lesions affords a sufficient criticism of such a procedure.

That amebae when combined with bacteria may cause intestinal lesions and even ulceration is now established. Furthermore, the experiments of Kartulis and Kruse and Pasquale with the contents of hepatic abscesses, supposed to be free from bacteria, are all but convincing, in so far as they may be supposed to prove the capacity of amoeba alone to set up such changes.

The attempt to cultivate *Amoeba coli* without admixture of bacteria has in all probability never yet been successfully carried out. The supposed positive experiment of Kartulis is now known to have been erroneous. Whether Celli and Fiocca have succeeded is still doubtful. In any case no satisfactory experimental production of amebic dysentery in cats or other animals has thus far been achieved with cultures of amebae free or relatively free from bacteria.

The pathological findings in amebic dysentery have been adduced as proving its specific character by Councilman and Lafleur, Kruse and Pasquale, and Kartulis. According to this view the intestinal ulcers in amebic dysentery begin as in infiltration of the submucous coat that leads to necrosis of the overlying membrane. The lesions, unless complicated by the presence of bacteria, are free from the products of purulent inflammation. The accompanying abscess of the liver exists independently of the presence of bacteria. Kruse and Pasquale, and Kartulis ascribe greater significance to bacterial association than do Councilman and Lafleur. Kartulis sees in the occasional diphtheritis

evidence of their action, while Kruse and Pasquale have followed them in their penetration into the coats of the gut, where they lie side by side with the amebae or even precede them in the invasion. Both bacilli and cocci occur, and wherever necrosis is found bacilli are sure to occur in groups and masses. "The amebae and bacilli together start the lesions in the intestine." (Kruse and Pasquale.)

The form of lesions here described does not entirely represent the disease as it appears in the tropics. Even Lafleur in a later communication says that the term "tropical" can be used only as a partial synonym for amebic dysentery, inasmuch as, on the one hand, the disease, though more frequent in the tropics, is by no means limited to those regions, while, on the other hand, there are undoubted cases of dysentery in the tropics which are not of the amebic form—a statement borne out by my own observations.

How far, then, have the foregoing results aided us in clearing up the hitherto obscure etiology of this protean malady? While epidemic, endemic, and sporadic dysentery have been subjected to bacteriological investigation, the chief work thus far done has been with the tropical variety. Although the actual number of cases of the epidemic disease which have been carefully studied is small, it is significant that, with two exceptions—the studies of Ogata and Calmette—the several different microorganisms isolated have all been bacteria which are normally present in the intestinal canal. The cultures have, it is true, undergone changes of virulence, but in other respects they have retained their ordinary biological and physiological properties unaltered. It would certainly seem *a priori* highly improbable that so severe and devastating a disease as epidemic dysentery should be due to microorganisms which are constant inhabitants of the intestinal tract. Moreover, when it is recalled how easily and under what great variety of conditions such accessions of virulence may be achieved, it would be remarkable that epidemics of dysentery are, nevertheless, relatively rare phenomena.

Turning to the tropical disease, we also observe that several microorganisms have been assigned as the causative agent. Chantemesse and Widai have described a bacillus not obtained since from similar cases; Arnaud, Laveran, and Celli, and Fiocca have seen in the colon-bacillus, modified in its pathogenicity, a sufficient cause. More weight, and with for greater justice, has been laid upon *Amoeba coli*. But this organism has been found more especially in chronic cases. Kartulis states that the catarrhal stage, which is common in the epidemic and sporadic disease, is uncommon in this form. If *Amoeba coli* is the organism most commonly present in the acute dysenteries of the tropics, the fact has not yet been conclusively established. However this may be, in Manila, where the organism is not infrequently present in the chronic disease, its absence in the very acute and often rapidly fatal cases of dysentery must be regarded as of significance.

From the preceding considerations the following conclusions seem warranted:

1. No bacterial species yet described as the cause of dysentery has an especial claim to be regarded as the chief microorganism concerned in the causation of the disease.

2. It is unlikely that any bacterial species that is constantly and normally present in the intestine or in the environs of man, except where the disease prevails

in an endemic form, can be regarded as the probable cause of epidemic dysentery.

3. The relations of sporadic to epidemic dysentery are so remote that it is improbable that the two diseases are produced by the same organic cause.

4. The pathogenic action of *Amœba coli* in many cases of tropical, and in certain examples of sporadic, dysentery has not been disproved by the discovery of amebae in the normal intestine and in diseases other than dysentery. While amebae are commonly present and are concerned in the production of the lesions in subacute and chronic dysentery, they have not thus far been shown to be equally connected with the acute dysenteries even in the tropics. In the former varieties, bacterial association probably has much influence upon the pathogenic powers of the amebae.

THE DYSENTERY OF JAPAN AND THE PHILIPPINE ISLANDS.

Every year, especially in the summer and autumn, dysentery prevails in Japan. Ogata and Eldridge have given the statistics of incidence and mortality in the years from 1878 to 1899:

YEAR.	CASES.	DEATHS.
1878.....	1,118	206
1879.....	8,322	1,487
1880.....	5,047	1,305
1881.....	7,001	1,837
1882.....	4,330	1,313
1883.....	21,172	5,056
1884.....	22,702	6,036
1885.....	47,377	10,690
1886.....	24,328	6,839
1887.....	16,125	4,244
1888.....	26,789	6,570
1889.....	22,893	5,970
1890.....	12,632	8,706
1891.....	46,358	11,208
1892.....	70,842	16,844
1893.....	167,305	41,282
1894.....	155,140	38,094
1895.....	52,711	12,959
1896.....	85,876	22,356
1897.....	91,077	23,189
1898.....	90,933	22,379
1899.....	125,989	26,709
	1,136,047	276,309

The epidemic studied bacteriologically by Ogata occurred in the province of Oita where in 1890, 801 cases occurred with 221 deaths, and in 1891, 8,390 cases with 2,163 deaths—an average mortality of from 26 to 27%. This epidemic had been preceded by sporadic cases in the previous winter, and in its spread showed a strikingly contagious character. The lesions in the intestine are described in one case, death having taken place on the eleventh day of the disease. The lower segment of the small intestine was hyperemic. The large intestine was greatly swollen so that the lumen was almost obliterated. The mucous membrane was hyperemic and presented a deep bluish-red color. The contents were chocolate-colored. The mucosa of the transverse and descending colon, and especially of the sigmoid flexure, showed small ulcers, the size of peas, which were so numerous as to give to the membrane a sieve-like appearance. They were also found, though in smaller numbers, in the descending colon and rectum. No large ulcers were present. The peculiar bacilli—staining by Gram, liquefying gelatin, and causing in animals, whether injected beneath the skin or into the rectum, hyperemia and ulceration of the intestinal mucosa—have been already described.

Ogata's decision was that the bacillus isolated was probably the cause of the epidemic of dysentery prevailing in Southern Japan.

I am not acquainted with a full description of the morbid anatomy of the dysentery prevailing in Japan. Schaubé, formerly of Tokio, in his "*Die Krankheiten der warmen Länder*," does not give a detailed account of the Japanese variety, but contents himself with the usual classification and description of the disease. The meager accounts may possibly be explained by the fact that necropsies are obtained in Japan only with great difficulty. Dr. Eldridge states that the lesions seen in "amebic dysentery" as described by Councilman and Laffleur are seldom met with. The common lesions are destructive, progressing from the surface downwards, associated with necrosis of the mucosa and croupous infiltration (diphtheritis). Perforation is unusual, the muscular coat offering a strong resistance to the pathological process.

The most recent bacteriological study of dysentery has been made by Shiga, to whose results I would ask especial attention. During 1897 the disease prevailed epidemically in Japan, 89,400 cases with 22,300 deaths (24%) being recorded from June to December. Out of a considerable number of cases occurring in Tokio, 36 were subjected to bacteriological examination by Shiga.

As was readily recognized by him, four points must be proved in the effort to show that an organism suspected of standing in etiological relation to any given disease is really the causative agent: (1) The organism must occur constantly; (2) it must be a species not present normally in the diseased part; (3) it must be pathogenic and produce in experimental animals lesions similar to those from which it was obtained; (4) it should in virtue of its pathogenic activity in man show the Widal agglutination reaction with the blood-serums of those who have suffered from the disease. From the series of cases examined there was obtained from the dejecta and intestinal contents and walls, and from the mesenteric glands, a bacillus which fulfilled all these requirements and which was regarded as the cause of Japanese dysentery, at least.

Before entering upon a description of this organism I should like to direct your attention to the dysentery prevailing in the Philippine Islands, especially in and around Manila. The report of the Surgeon-General of the Army for 1899 contains a tabulation of diseases, observed among the American troops, during the first four months of the American occupation of Manila. In it the dysenteries are included with the diarrheal diseases. The total number of cases reported is 445, the death-rate being 0.48%. The comment made is that "the malarial diseases exceed their prevalence in the United States in the proportion of 370 to 96, and the diarrheal diseases in the proportion of 445 to 116, or about 4 to 1 in both instances."

This compilation fails to give an adequate idea of the extent, severity, and mortality of dysentery in Manila. Although, unfortunately, figures are not obtainable, I am convinced, after nearly three months' residence in Manila, that the enteric diseases, of which dysentery was the most frequent and important, were the chief causes of disability and mortality among the land forces of the American army.¹

¹ The studies on dysentery here recorded were made by a commission consisting of Dr. L. F. Barker and myself, sent out by the Johns Hopkins University to study the diseases prevailing in the Philippine Islands. To this commission were attached Messrs. Joseph M. Flint and Frederick P. Gay, who were, at that time, members of the Johns Hopkins Medical School.

The disease appears in two main forms, acute and chronic dysentery. The stools and intestinal contents at autopsy were scrutinized for amebae. So far as regards the acute cases these organisms were absent or very difficult to find in the fresh stools and in the intestinal contents immediately after death. In the chronic forms of the disease ulcers were present in the mucosa and submucosa; the lesions were confined to the large intestine, the coats of which were greatly thickened; at times large sloughs of the mucous membrane, partly detached, were encountered. Amebae were commonly present, but were variable as to actual occurrence and numbers. Large hepatic abscesses, usually single, were encountered in a number of these cases. Amebae were not always found in the contents of these abscesses; sometimes bacteria were present alone or associated with amebae. Amebae not distinguishable, except by the absence of specific inclusions, from those in the stools of human cases exist in the dejecta of monkeys liberated from captivity and now at large in Manila.

The morbid anatomy of the chronic disease agrees in part only with that of "amebic" dysentery. I shall draw attention later to another form of the chronic disease.

The pathological changes in the acute cases differ widely from those of the chronic affections. I shall now give in brief the condition of the intestines in several cases of acute dysentery. The patients were American soldiers.

CASE 1.—Death on the sixth day of the disease. The entire large intestine from the cecum to the rectum is dilated and the walls of the gut are thickened. The mucous membrane is swollen, its consistence is much increased and the normal folds are thrown into elevated, coarse corrugations. The general color of the mucous membrane is deep red, but there are present many brighter spots, evidently due to hemorrhage. No distinct false membrane is to be made out, but here and there are scattered white elevations, which, after the intestine has been washed, become more prominent and can be removed only with some difficulty, small defects in the membrane being left behind. In the fresh state ulceration was not made out, but after the washing referred to, there is found in the lower portions of the sigmoid flexure minute, sieve-like points, with perfectly sharp edges, representing defects which lead into the submucosa. The smallest of these openings are the size of pin-points, the largest about 2 mm. in diameter. The contents of the intestine showed no amebae.

CASE 2.—Death on the fifth day of illness. The small intestine, excepting the lower end of the ileum, which is deeply congested and swollen, shows no alteration. The serosa over the large intestine is injected, but is otherwise normal. The large intestine is much thickened and its consistence is increased. On opening the gut the contents are found to be dark or nearly black in color, an appearance probably due to the administration of bismuth. The mucous membrane extending from the rectum to the ileocecal valve, and beyond the valve in the ileum for a distance of 4 cm., is congested, swollen, and hemorrhagic. Scattered here and there on the surface are elevated, white, irregular points and small, flattened areas, which suggest a pseudomembrane, but which cannot be absolutely identified as of such a nature. The normal velvety character of the mucous membrane is lost. No ulceration can be made out and the lesions seem to be chiefly in the mucosa and submucosa. Particularly conspicuous is the wide diffusion of the lesions, no part of the mucous surface within the limits defined having escaped. The mesenteric glands are congested and moderately swollen. Although amebae had been found in the evacuations two days previous to death, they could not be demonstrated in the intestinal contents at autopsy.

CASE 3.—Death after an illness of 6 days. The large intestine is markedly dilated and the serous coat is much injected. The contents of the large intestine are represented

by a grumous, pink, pulpy material. The mucous membrane is swollen and hyperemic, and presents a striking granular appearance due to exudate upon the surface; many areas of hemorrhage are also observed. The entire mucosa of the large intestine is implicated in this process. Ulceration is not present. The mesenteric glands are swollen, congested, and hemorrhagic. The spleen is moderately enlarged. Amebae were not demonstrable in the intestinal contents.

The three cases which have been selected do not agree with amebic dysentery as hitherto described. In only one were amebae found in the stools, and even then they could not be demonstrated in the intestinal contents, obtained immediately after death, which took place two days after the first examination. The stools consisted, as was the rule in the acute disease observed in Manila, of mucus and blood. The microscopical examination revealed epithelial cells, red blood-corpuscles, a moderate number of bacteria and many amebae. On the same day injections of quinin were begun, ipecac being administered by the mouth. The note 24 hours later states that the stool contained mucus but less blood. Epithelial cells were still present and the bacteria appeared in greatly increased numbers. No amebae could be discovered. Death took place on the day of this examination.

In their pathological histology also the acute dysenteries differ from the amebic form. The histological changes appear in the mucous membrane, submucosa and muscularis, being most marked in the former situations. Those of the mucous membrane consist of coagulative necrosis with exudation of fibrin and polymorphonuclear cells. The fibrinous and cellular exudate may entirely replace the glandular layer, or here and there a gland may be preserved. The pseudomembrane is a close-meshed network of fibrin enclosing multinuclear, often fragmented, cells. No bloodvessels are to be distinguished, but a variable number of red blood-corpuscles are mingled with the exudate and lie free upon the surface. The muscularis mucosa is not always distinguishable—indeed it is frequently lost in the exudate. The submucosa is always much altered. From the changes found in it, it is evident that to them is chiefly due the thickening of the gut. The part most affected is the layer next the muscularis mucosa. Here are found hemorrhages of variable size, while in the interstices of the tissues some fibrin appears. More marked, however, are cellular accumulations, which are present, not uniformly, but in irregular areas. The deeper layers of the submucosa show similar cellular infiltrations, although the amount is less striking. On the other hand, at these levels the quantity of fibrin is greatly increased and hemorrhages are numerous.

The character of the cellular exudate is quite uniform. Excluding the red blood-corpuscles, the new cells consist chiefly of plasma-cells. These are collected into foci, often about bloodvessels, veins and arteries, but sometimes occur in small groups or singly. There can be no doubt that these are identical with Unna's plasma-cells; they show the reticulated nucleus, often placed excentrically, and the fine blue granulations of cell-protoplasm in eosin and methylene-blue staining. As the deeper levels of the submucosa are reached, hemorrhages and fibrin are abundant. The size of the foci of plasma-cells gradually diminishes. At the muscular border they have about disappeared. Among the plasma-cells a variable number of eosinophilic cells may be distinguished.

In the submucosa, infiltrations, hemorrhage, and fibrin

formation take place also beneath an intact or almost intact mucous membrane. The nature of the cellular infiltration may be identical with that already described, but in addition accumulations of lymphoid cells may frequently be seen. These exist in the layer of the submucosa immediately next the muscularis mucosae; the deeper cells resemble plasma cells.

The bloodvessels of the submucosa may be patent and congested, the blood containing an excess of white elements; or they may show recent leukocytic and fibrinous thrombi. Hyalin degeneration of the vascular walls was not encountered. Large spaces in the submucosa may contain fibrinous clots; these are probably dilated and thrombosed lymphatic vessels.

The muscular coat shows only hemorrhages, which may be of large size, although they are usually smaller than in the submucosa. The peritoneal tunic is usually unaltered.

From this brief description it is evident that the main pathological changes take place in the mucous membrane and submucosa and it is also clear that the 2 tunics may be affected simultaneously or the submucosa may suffer pathological alterations without involvement of the mucosa. So far as could be ascertained from the material studied, in contradistinction to the condition observed in "amebic" dysentery, ulceration did not begin in the submucosa, but any defect which may have occurred resulted from exfoliation of the necrotic mucosa and the attached pseudomembrane.

It is interesting in this connection, to emphasize the fact that the polymorphonuclear leukocyte plays a very insignificant part in the process of infiltration in the submucosa, whereas in the affected mucous membrane it is much in evidence. On the other hand, the bloodvessels of the submucosa contain those cells in increased numbers, and the cellular and fibrinous thrombi are rich in them. It would appear, therefore, that these cells do not leave the vessels in the submucosa as readily as those of the mucous membrane. That the bloodvessels of the submucosa suffer great injury from the pathogenic agent is shown by the free hemorrhages and the fibrinous exudation.

Bacteria are abundant in the fibrinous exudation in the mucous membrane. The chief varieties distinguishable are cocci and bacilli. In specimens stained by Gram's or Weigert's methods, large numbers of cocci, in short chains and groups, can be made out. In other specimens, stained in Unna's alkaline methylene-blue, besides the cocci many bacilli may be seen. These are quite uniform in size; they present the morphological characters of the colon-typhoid group, from which they could not be distinguished in sections of tissue. While the bacteria are so abundant in the necrotic mucous membrane, diligent search failed to exhibit either bacilli or cocci in the infiltrated areas of the affected submucosa. The conviction is therefore forced upon one that the lesions in the submucosa are toxic in origin. Amebae were not discovered in the sections.

THE BACTERIOLOGY OF PHILIPPINE DYSENTERY.

In the study of the bacterial flora of the disease acute and chronic cases were utilized. The methods of procedure varied only slightly in different cases. The acutely ill being in bed, the evacuations were collected in bed-pans, which a short time before had been carefully scalded. The patients who were about the wards were taken to the laboratory, where cultures could be

made immediately from the contents of the rectum. The fatal cases were subjected to autopsy immediately after death. The large gut at different levels was burned through with a hot knife, and cultures were made before disturbing any of the viscera. Plate cultures in agar-agar were employed. The average number of plates made from a single case was twelve. The material was mixed with bouillon, so as to afford the advantage of a relatively large amount for plating. It was frequently obtained from several different portions of the evacuation or from several levels of the intestine. Only such plates as contained well-separated colonies were utilized. Control microscopical examinations of the evacuations and intestinal contents were made. It may be mentioned that cercomonades and trichomonades were very common in the diarrheal stools. They did not appear to be of pathological significance.

From the separated colonies, agar-slant cultures were made. The growths of the pyogenic cocci as well as those of *B. pyocyaneus* were not pursued further. The former was never absent, the latter was rarely present. The bacillary colonies, which occurred with regularity in the acute disease, could be distinguished according to two distinct types. Their properties are as follows:

Type I.—Bacillus of the average size of *B. coli* communis. There is variation in length; almost none in thickness. The individuals are usually separate; sometimes they are united in pairs, but only very rarely do they occur as filaments. The ends are slightly rounded. The bacillus shows moderate motility; Gram's stain is negative.

Growth takes place upon all culture mediums at the room temperature, but better in the thermostat. Gelatin is not liquefied. The colonies resemble those of *B. typhosus*, being more nearly like them when first isolated from the dejecta than after a period of cultivation outside the body. After many months of such saprophytic growth the colonies become thicker, exhibit a moist surface and are less translucent. The strokes upon agar-slants show a similar alteration. At first the growth extends but little laterally, but later on it becomes 2 to 3 mm. in width, and generally shows distinct indentations at the edges. Upon gelatin the colonies are more delicate; the stab extends along the line of puncture only, spreading very little at the surface of the medium.

On potato growth it takes place along the line of inoculation and spreads beyond. After some days it is a little elevated and of a pale brown tint. On unfavorable potatoes the growth is slight, moist and membranous, resembling, except for the greater amounts of moisture, that of *B. typhosus* when typical.

Sugars—glucose, lactose, and saccharose—are not fermented gaseously. In glucose media a moderate acid-production takes place.

Bouillon is clouded diffusely and a sediment forms. There is no production of a pellicle.

Litmus-milk assumes, after 24 to 72 hours, a faint lilac tinge. After the lapse of from 6 to 8 days alkali begins to be produced, which increases in amount until the litmus is rendered deep blue in color. No coagulation of the milk ensues.

Indol is not always formed. Even in sugar-free bouillon it may fail to appear, or it may be produced in small quantities only.

Suitable cultures of this organism, when tested for the agglutination reaction with the blood serum of

persons suffering from dysentery—the host or another individual—give, in many cases, a positive result.

The bacillus is pathogenic for the ordinary laboratory animals. It is abundant in the acute cases in which it may be the predominating organism; it becomes more difficult to find as the cases progress towards recovery or chronicity. In the ordinary chronic dysentery of Manila, in which amebae are commonly encountered, it was not found. It can be cultivated from the dejecta during life, and the intestinal contents, mucous membrane and mesenteric glands in fatal cases.

Type II.—Bacilli which are present in all instances. In the acute cases they may not predominate, being less numerous than the members of Type I. In all others it is the predominating bacterium. The properties vary somewhat, but agree well with those of the group *B. coli communis*. The main variations relate to extent and rapidity of growth upon the several culture mediums, the rapidity with which litmus-milk is reddened and coagulated, and the amount of indol produced. The sugars are broken up with the formation of gas. The morphology is also similar to that of *B. coli*; some specimens are motile at the end of 24 hours; in others motility was not demonstrated.

In agglutination tests the results varied according as the blood of the host or of another individual was employed. With that of the host there was frequently a reaction in low dilutions; with that of another person the reaction was rarely and very inconstantly obtained. The pathogenicity was not tested extensively.

The practical operation of separating the several kinds of bacilli which grew in the plates was to inoculate glucose-agar stab-tubes from the different colonies. In those tubes which, after 24 hours at 37° C. showed no gas, the organisms were likely to conform to Type I.

Before proceeding to the assumption that this organism was concerned with the production of the intestinal lesions of dysentery occurring in Manila, it was necessary to establish its absence from the stools of healthy persons and of those suffering from other diseases. Strong presumptive evidence of its being an unusual inhabitant of the intestine of man may be gathered from the facts already known concerning the ordinary intestinal flora. But as such observations would not suffice for a new region and under new conditions, the organism was searched for in other persons who had been in close association with those suffering from dysentery and also in inhabitants of other parts of the Island of Luzon. The organism was not demonstrated in healthy dejecta or in evacuations of persons (native Filipinos) suffering from beri-beri. A further argument in favor of its restricted distribution is furnished by its absence from cases of chronic dysentery or the marked reduction in the numbers present.

Pathogenicity.—The pathogenicity of the bacillus Type I was studied, soon after its isolation, upon mice and monkeys in Manila, and upon various animals in this country with cultures brought from the Philippines.

Monkeys.—Subcutaneous inoculation gives rise to a swelling from which the animal suffers no inconvenience and quickly recovers. Monkeys which were given croton oil and, after purging had been established, 10 cc. of a bouillon culture through a stomach-tube, soon recovered from the effects of the purge, and no further results could be noted.

Mice are susceptible to subcutaneous and intraperi-

toneal inoculations. Death takes place in from 24 to 48 hours—more rarely after several days—the reaction varying according to the dose and the mode of inoculation. The site of puncture shows edema and, in the case of injections made beneath the skin, a hemorrhagic exudate. Inoculation into the peritoneal cavity gives rise to a variable amount of faintly turbid exudate and small white flakes of leukocytes; the pleura contains an excess of clear fluid which is often present also in the pericardium; the serous vessels are injected and small hemorrhages may occur more especially in the subcutaneous tissues. The superficial lymphatic glands are swollen and congested or hemorrhagic; the spleen is enlarged, the kidneys and adrenal glands are congested; the lungs show a marked congestion and the intestines contain an excess of glutinous contents. Coverslips from the peritoneal and pleural exudates show bacilli, often in large numbers, and polymorphonuclear leukocytes. These cells frequently show engulfed bacilli. Cultures prove a general invasion of bacilli with relatively smaller numbers of organisms in the spleen and heart's blood.

Guinea-pigs react in much the same way as mice, larger doses being required to produce fatal results, while the bacilli show less tendency to invade the internal organs. Subcutaneous injections cause a local swelling consisting of pus-corpuses, serum, and blood; the superficial lymph-glands become swollen, and an exudate appears in the peritoneal and more rarely in the pleural cavities. Intraperitoneal inoculations give more characteristic results. Death took place in from 1 to 6 days depending upon the source and amount of the culture. The inguinal and axillary lymphatic glands are enlarged and reddened; the peritoneal cavity may contain glutinous fluid and floating whitish flakes of pus-corpuses, or with little fluid, there may be grayish-white solid exudates of considerable size over the liver, spleen, and intestines. The bloodvessels are injected, the small intestines are filled with a soft glutinous matter, ecchymoses occur in the mucosa of the intestines, and the Peyer's patches may be swollen and reddened. If death occurs late the swelling of the Peyer's patches may have disappeared and be represented by the "shaven-beard" appearance. The liver exhibits areas of coagulation-necrosis of considerable size; the adrenals and the kidneys are congested. The pleural cavity frequently contains an excess of clear fluid and the lungs are mottled. The pericardial vessels are also injected and the sac contains an increased quantity of clear fluid. The distribution of the bacilli varies. With moderately virulent cultures they occur only in the local exudates in the peritoneal and pleural cavities. In rare instances, indeed, they may disappear even from the abdominal cavity, be greatly reduced in numbers, absent from the internal organs and blood or occur there in very small numbers. This disappearance may have taken place when death has occurred as early as 24 hours after inoculation. Larger doses or intensified cultures give rise to a moderate invasion of the blood and organs. If the autopsy on these animals is delayed, especially in warm weather, an increase of bacilli in the blood rapidly takes place, so that erroneous results may be obtained. Within the local exudates the bacilli are surrounded by capsules and are often contained within polymorphonuclear leukocytes. The bacilli can also be cultivated from the fluid portions of the intestinal contents. The ingestion of cultures gives rise to no results unless the stomach-contents are first

neutralized; in the latter case death may occur; the small intestine is hyperemic; the contents are hemorrhagic and mucoid and the bacilli can be cultivated from them.

The rabbit usually responds with a localized swelling at the site of the subcutaneous injection from which the animal usually recovers. When the injection results fatally the local infiltration resembles that in the guineapig, being, however, more marked than in that animal.

Cats also succumb to subcutaneous injections. Feeding alone produces no result. If, however, croton oil is first administered and the culture is then introduced into the stomach, diarrhea sets in, the bacillus is recoverable from the dejections and death may result. In the last case the mucosa of the large intestine is hyperemic and secretes an excess of mucus. The dog may succumb to simple feeding of the cultures. In positive instances diarrhea sets in, the appetite is lost and death may take place in 5 or 6 days. The mucous membrane of the intestine is hyperemic; hemorrhages occur, and the cavity of the gut contains a great excess of mucus from which the bacillus may be recovered.

The dead cultures are also toxic. Certain results of the inoculations into guineapigs suggest that the fatal effects are due to a toxic agent rather than to an infection *per se*. Cultures killed by exposure to temperatures of 60° C. for from 15 to 20 minutes are still active. In the course of certain immunization experiments one of the goats of a series succumbed to inoculation with dead cultures. On November 22, 20 cc. of a bouillon culture, killed by heating to 60° C., was given under the skin of the shoulder. Considerable induration developed at the site of inoculation; diarrhea set in from which the animal seemed to recover. On November 29, a second injection of 20 cc. of the culture was given; on the next morning the animal was dead. The autopsy showed edema over the site of inoculation. The nates were covered with thin, partly dried fecal matter. The mucous membrane of the gut was hyperemic and presented numerous punctiform hemorrhages.

Dead cultures injected into rabbits and guineapigs cause: (1) Elevation of temperature; (2) symptoms of intoxication (especially in guineapigs) which may come on within two or three hours after the injection; and (3) in rabbits, rapid recovery with a localized and decreasing swelling; in guineapigs, similar phenomena or death in a few hours or after 4 to 6 weeks. In the last instance the animals show great emaciation. In the case of those that have recovered from the immediate results of the injection agglutinating properties for the bacilli appear in the blood.

Has this Bacillus Been Found in Other Epidemics of Dysentery?—If the bacillus described is of significance in the etiology of dysentery it must occur with regularity in the disease. Whether or not it will be found to have the distribution that is necessary in order to establish this relationship, can only be determined from studies carried on in widely different places and in all forms of the disease. That the bacillus is identical with the organism obtained by Shiga in the epidemic of dysentery which prevailed in Japan, there can be no reasonable doubt. In morphological, cultural, and pathogenic characteristics the two organisms are indistinguishable.

Through the courtesy of Dr. J. H. Musser I have been enabled to study, bacteriologically and pathologically, a case of chronic dysentery contracted during

the Spanish war in Puerto Rico. The patient, a soldier, entered the hospital of the University of Pennsylvania in December, 1899. His dysentery dated back some months; the movements were frequently examined for amebae with negative results. A brief abstract of the autopsy protocol is as follows:

The body is that of a greatly emaciated man about 35 years old. Dorsal decubitus. The peritoneal cavity contains a small amount of reddish fluid. The colon is thickened and in the peritoneal surface, especially along the sigmoid flexure, shows dark points and lines of discoloration. The rectum and sigmoid flexure are contracted; the transverse colon, on the other hand, is dilated. The mucosa of the large gut is thickened throughout; in addition there are small, recent hemorrhages into its substance. There is no pronounced ulceration; the mucous membrane presents a granular aspect; there are superficial areas denuded of epithelium, and others which are slate-colored and show dark pigmentation. The submucosa is not especially thickened except in the lower part of the gut, where there is much contraction. The mucous membrane of the transverse colon is edematous; the cecum is less affected than the colon, while the small intestine has entirely escaped. No pseudomembrane is present except upon a small portion of the lower parts of the sigmoid flexure.

The bacteriological examination made from the contents of the hepatic and sigmoid flexures gave growths in which the two general types of bacilli already described were contained. The predominating form agreed with Type II (*B. coli communis* group); in addition, there were colonies of an organism which in morphological, cultural and pathogenic characters and in the agglutination reaction corresponded with the variety of bacilli represented by Type I. The histological appearances in this case differ from those in the acute disease and equally from those of the amebic variety. The changes are found more particularly in the mucosa and submucosa and represent, it would appear, a later stage in the course of the acute disease. Before describing the other changes it should be mentioned that a striking feature in the case is the congestion in the mucosa, submucosa, and muscularis. Numerous large veins, distended with blood, occupy the field of the microscope. Whether these vessels are newly formed cannot be stated positively; but they certainly are many times larger than any preexisting vessels normally met with in the same situations. In a few places the surface of the mucosa shows a necrosis of the hyalin or coagulative variety, there being no appearances of exudative fibrin in these areas. The necrotic tissue is dense and hyalin. These necroses do not include the entire thickness of the mucous membrane, but cap superficial foci. There can be no doubt that this tissue-death indicates an exacerbation of the acute disease, with which, indeed, the great congestion may be partially associated.

The chief and, as I take it, characteristic changes in this stage of the disease are proliferative in character. The mucous membrane is not markedly altered in volume. Its structure is, however, greatly modified. Very few glandular structures remain. The membrane is represented by a mass of spindle and epithelioid cells together with a reticular and coarser intercellular network, enclosing the remains of the crypts of Lieberkühn. The submucosa, also, shows a new growth of tissue, in which, however, appear much more advanced changes.

The submucosa is composed of dense, almost hyalin, and structureless tissue, taking a vivid eosin stain and enclosing foci of epithelioid cells. The hardening and distortion of the gut were, doubtless, caused by this new growth of tissue and its subsequent contraction. The dilated bloodvessels, mentioned above, occupy a prominent place in this coat. A variable number of lymphoid, plasma, and eosinophilic cells occur, especially about the veins.

The muscular coat is also the seat of a multiplication of connective-tissue cells, which is shown by the masses of epithelioid cells separated by muscle-fibers, as well as an increase in foci of the fibrous tissue.

Blood-pigment is present both in the muscular and the subperitoneal coat.

The careful bacteriological studies in Egyptian dysentery, made by Kruse and Pasquale, contain numerous references to typhoid-like bacteria. Critical examination shows the majority to belong to the groups of *B. coli communis*. The typhoid characteristics depend merely on cultural resemblances—most marked in growths on agar-agar. Fermentation and their effects upon milk eliminate the suspicion that they may be typhoid bacilli, or the organism obtained by Shiga in Tokyo, or by myself in Manila. Still other examples of bacilli, similar to and possibly identical with *B. dysenteriae* (Shiga), have been found in dysentery, though they are not suspected of standing in any etiological relation to it. Pansini studied 4 cases of abscess of the liver, 3 of which followed dysentery. The bacilli, which were isolated, resembled *B. typhosus*—indeed, Pansini could not distinguish between the two series. Babes also, although only in a single instance, isolated such an organism from a case of dysentery.

Since the publications of Shiga's studies, Escherich and Celli have both attempted to show that the organisms obtained from their respective epidemics of dysentery are identical with the *B. dysenteriae*. In both cases they have proceeded upon the false assumption that Shiga's microorganism was a variety of *B. coli communis*, whereas, in point of fact, it is much more nearly related in its cultural and physiological properties to *B. typhosus*.

The question naturally arises, In what ways does it differ from *B. typhosus*? Comparison of the Eberth-Gaffky and Shiga bacilli show the criterions of difference to be by no means numerous. The main features, however, are as follows: The latter shows less marked motility when first isolated and a tendency to lose motility rapidly in artificial cultivations; it displays a more uniform generation of indol; after a brief preliminary acid production in milk it gives rise to a gradually increasing alkalization; it is inactive to blood-serum from typhoid cases; but reacts with serum from dysenteric cases to which *B. typhosus* does not respond.

The Agglutination Test.—While the absolute value of this test in determining the specificity of bacteria may be open to doubt, its use in differentiation is now unquestioned. Undoubtedly there are limits to its usefulness, and experience (gained especially in typhoid fever) has shown that the changes upon which the property of the blood-serum depends for its evolution in certain instances may fail to take place. The tests in the case of the bacillus isolated in Manila were made at the time with blood obtained from acute and chronic cases of dysentery, occurring there and in the surrounding country. For carrying out the tests the blood was obtained in capillary tubes from the lobe of the ear of the

living, and in larger quantities directly from the cavities of the heart by means of sterilized pipets from the fatal cases of dysentery. The tests were made under the microscope and by growing the organisms in mixtures of bouillon and blood-serum. After our return to this country, the blood-serum from the case of Puerto-Rican dysentery was employed and gave positive results. Through the courtesy of Assistant Surgeon Craig, stationed at the Presidio at San Francisco, I obtained capillary tubes filled with blood taken from convalescents and other soldiers suffering from chronic dysentery acquired in the Philippines. The present status of the agglutination reaction may be summed up as follows:

Positive results were obtained with cases definitely known to have been infected with the microorganism in question. The results obtained from the blood derived from chronic dysentery were more variable. Dr. Osler has written me of his experience. In several cases of amebic dysentery which have come under his charge in the Johns Hopkins Hospital, the blood-serum failed to produce the reaction with the bacillus obtained in Manila; in one case of the Puerto-Rican disease a positive reaction was given.

The above results tend to emphasize the distinction of types of dysentery occurring in the tropics. They further tend to confirm the possibility that the acute dysenteries are caused by *B. dysenteriae*. To what extent the organism is concerned with the production of chronic dysentery remains to be established. That we must recognize a chronic form of tropical dysentery that is not in its entire course associated with the presence of amebae in large numbers, and that possesses totally different pathological lesions, is certain. I am inclined to the opinion that this type is not the commonest form of chronic tropical dysentery, and that it is less frequent than the amebic type. As it appears to be the form that gives a positive serum reaction with *B. dysenteriae*, its extent and distribution may now be open to investigation.

Bearing directly upon these considerations are the results of Lieutenant Strong's studies continued after our departure from Manila. He writes: "After you left we had a large number of acute cases of dysentery. It seems certain that this form, which we have begun to speak of as *acute infectious dysentery*, is independent of amebae. I have now records of 14 cases (not all were fatal) which I studied bacteriologically. From the stools in all of these, there has been obtained a bacillus which agrees with the organism obtained by you. I have also obtained the organisms from the mesenteric glands in three fatal cases. In one case of acute dysentery with secondary acute fibrinous peritonitis I obtained it from the exudate. The agglutination reaction is not invariable. Amebae were never demonstrable in any of these 14 cases. On the other hand, in every case with certain anatomical lesions we always find the amebae. In some cases of dysentery in which the amebae were absent and the bacilli present, that have lasted four to five weeks (one case lasted nearly two months) and then resulted fatally, we see a continuation of the same process that is observed in the acute fatal cases. The lesions are those of necroses of the mucous membrane and induration of the gut."

Protective Inoculation and Serum Therapy.—It is not unreasonable to hope that with the discovery of the specific cause of dysentery, particularly if it proves to be a bacterium capable of being artificially cultivated, means will be found by which protective inoculation

may be carried out with effect and safety. The fundamental conditions underlying such immunization are now fairly established, and two general methods of accomplishing such results are open to investigation. In the first place, an active immunization may be achieved through the use of cultures of a determined grade of activity; in the second the serum of animals may be employed either as a therapeutic agent or to provide a passive immunity.

It has been found possible, through the use of cultures destroyed by heat or the addition of chemicals (trikresol), to protect small animals from subsequent inoculations with virulent bacilli. Larger animals, such as the goat, when treated first with the dead and afterwards with the living cultures, develop a gradually increasing resistance to the inoculations; their blood-serum assumes highly agglutinating qualities for the bacillus, and co-incidentally acquires protective and healing properties. My own experiments relating to this topic have been carried out on small animals only. Shiga, has, however, been able to test the serum upon human cases. Dr. Eldridge in his report gives the following figures: Up to November 1, 1899, Shiga had treated with the serum, in 1898 in Laboratory Hospital, 65 cases, death-rate 9%; in 1899 in Laboratory Hospital, 91 cases, death-rate 8%; in 1899 in Hirowo Hospital, 110 cases, death-rate 12%. During the same period of 1899 there were under ordinary treatment at Tokyo, at Hirowo Hospital, 116 cases, death-rate 37.9%; at Hirowo Hospital, 53 cases, death-rate 37.7%; at Komagome Hospital, 398 cases, death-rate 34.7%; in private houses, 1,119 cases, death-rate 28.5%.

I should, however, expect greater benefit from a species of vaccination, especially to those exposed to the endemic or endemo-epidemic dysentery of the tropics. The encouraging results of the injections of the dead bacilli of Asiatic cholera and typhoid fever render justifiable the use of a similar procedure in persons exposed to dysentery. The practical details of such inoculations will, of course, be established only after trials, preferably upon human beings who are anxious to submit to this method of treatment. I have found it possible to prepare cultures which after being killed possess a definite degree of toxicity for guineapigs. The only examples of an experiment upon man yet available is that performed by Shiga, who directed that about $\frac{1}{2}$ of an agar-culture, suspended in bouillon and killed by heat, should be injected into the subcutaneous tissues of his back. The immediate results of the injection were pain in the head, slight chill and fever, and local infiltration. After five or six days—the symptoms having in the interim entirely disappeared, except for some slight swelling—this area of infiltration increased and called for incision. The subcutaneous tissues were found thickened, indurated, and infiltrated with pus, which was sterile to cultures. The local lesion, similar to those in animals, was, it is thought, produced by the toxic substance contained within the dead bodies of the bacteria. Immediately after incision, all disagreeable symptoms except the local infiltration disappeared gradually.

If this experiment can be taken as an index, the poison of *B. dysenteriae* is more active than the analogous substance contained in the bodies of the typhoid and Asiatic cholera organisms. This objection, if true, could be eliminated by dosage, or, if necessary, by combining the vaccine with immune-serum, as has recently been recommended by the German Plague

commission in carrying out the inoculations with the plague bacilli. Shiga's blood-serum, 10 days after the injection, showed active agglutination of the bacilli.

An interesting, if somewhat disagreeable, accident was experienced by one of the laboratory assistants in Baltimore. In studying the acid production of the Manila bacillus a small quantity of fluid culture was aspirated into the mouth. The culture was expectorated and the mouth rinsed with a weak carbolic-acid solution. Notwithstanding this precaution a severe diarrhea, with bloody and mucous stools, pain and tenesmus developed within 48 hours. I was in Philadelphia at the time and the scientific ardor of the patient was so greatly depressed as a result of his discomfort and suffering that cultures were not made from the dejections, nor was I notified of the accident until several weeks afterwards.

Very little remains for me to say at this time. It is only natural to ask whether the foregoing considerations justify a belief in a specific organism of dysentery. My own sense is against that belief, although it must be conceded that the varieties of the disease are fewer than the clinical and pathological-anatomical conceptions of the time would lead one to suppose. Excluding the sporadic cases, which need a much closer bacteriological study than has been yet accorded to them, it is entirely possible that two specific organisms may be responsible for the epidemic and endemic diseases *per se*. I think that I have shown that tropical dysentery consists of a bacillary and an amebic form, separable in their early and their later stages by their clinical histories, their etiology and pathological anatomy. It is important to know whether the epidemic disease is more uniform in its causation and pathological anatomy. The studies of the Japanese disease by Shiga are highly suggestive of this conclusion, but additional observations will be required before we can accept as final his conclusions.

New Staining Method.—Yamagiwa (*Virchow's Archiv*, Band 160, Heft 2) has devised a new method for staining the neuroglia, which, given briefly, is as follows: The tissue, cut in very thin sections, is hardened in Müller's fluid for about a month, changing the fluid in the beginning, daily for 5 or 6 days. For this solution the tissues are transferred directly, without washing in water, into absolute alcohol, where they remain for from several days to a week, the alcohol being changed daily. After imbedding in celloidin and cutting, the sections are stained in a concentrated alcoholic solution of eosin for 12 or more days, then in a concentrated watery solution of anilin-blue for from 4 to 6 hours, then differentiated in dilute alcohol rendered feebly alkaline with a 1% potassium hydrate solution. The deep-blue sections become reddish-brown. They are then washed in distilled water and the excess of blue removed in diluted alcohol. The sections now are reddish. They are then dehydrated in absolute alcohol, cleared in oil of origanum, and mounted in balsam. Thus treated, the axis-cylinders are deep-blue, the glia fibers and red blood-corpuscles dark-red, the myelin sheaths bright-red, the protoplasm of the glia cells pale-violet, the bodies of the ganglion cells pale bluish-gray with greenish granules, connective tissue fibers, adventitia, intima of bloodvessels sky-blue or pale greenish, the media bluish-red, the nuclear membranes all bluish. Regarding the nature of neuroglia fibers, Yamagiwa believes, on the basis of his results with the new stain, that the fibers are differentiated intercellular substance derived from the glia cells. This is practically the view of Weigert. He finds, however, that the fibers are not all entirely divorced from the cells, but that they generally touch the cells at some point. [D.R.]

A Suggestion to American "Ophthalmotricians."

—During the recent gathering of ophthalmologists at Paris, in connection with the International Medical Congress, an American oculist amused himself by observing the adjustment of the spectacles and eyeglasses worn by these masters of the science and art of optics. One American was present with properly fitted spectacles; of the remainder, the few who wore glasses must have been served by blacksmiths or shoemakers instead of opticians. And yet these scientific men had shoes that were made for their feet, they did not wear their collars over their ears, and their hats were suited to their heads. Everywhere in Europe the American dentist is in evidence, and we suspect those "stomatologists" without American diplomas have scant pickings. Can anyone explain why the European oculist is not only ignorant of practical refraction, but positively scornful of it? There is, probably, not a scientifically prescribed, surely not a properly adjusted, pair of glasses in all Europe. One of the greatest English physicians recently said he was convinced that headaches were never caused by eyestrain. Another said, "We have no ocular muscle troubles; how is it that you Americans have so many?" The answer was, that misfitted glasses probably gave the proper prismatic correction. We have been guilty of believing that the American "ophthalmotrician," in his desire to be a physician without a diploma, was indifferent to the scientific adjustment of glasses. We are inclined to hedge and advise him to emigrate and play medical missionary to our professional continental confreres. Two excellent results would follow his expatriation.

Filters as Microbe Breeders.—Many hotels, office buildings and other institutions throughout the land are supplied with mechanical filters which are generally supposed to purify the drinking-water used in the respective places, and upon which special stress is laid in all announcements pertaining to them. That most of these filters are actual detriments has been clearly demonstrated by the bacteriologist of the Buffalo Health Department, in a series of examinations covering a period of one month. Samples of water were taken daily from the city reservoir, from ordinary taps, and from taps the water of which had passed through a mechanical filter. This filter was established in the basement of a building for which it was intended to be

used, of sufficient capacity to filter all the water required in the building, and connected with the main supply-pipe, so that filtration was carried on under continuous pressure. The number of bacteria in the reservoir samples ranged from 180 to 220 per cc., in the ordinary tap water from 160 to 560 per cc., and in the filtered water from 1,180 to 3,800 per cc. This is not surprising; it is astounding! It is a matter to which public attention cannot be too strongly directed. Any filter which will multiply the danger from drinking-water seventeen times, while ostensibly minimizing the danger, is worse than the most fatal pestilence, of whose existence the public is aware and which it can avoid. This filter clarified the water, and that was about all that could be said in its favor, while apparently the number of bacteria increased with the length of time the filter was in use, making it a veritable germ-breeder. Regular tests should be made of all filters, and those found ineffective or detrimental should not only be condemned, but their sale prohibited, on the same principle as that of unsanitary food-stuffs. This is a subject in which few people are proficient. Hearing and reading so much about the necessity of water-filtration, the average person assumes that any filter answers the purpose, and no one can tell which filter is good or bad except by scientific tests.

Tonsorial Hygiene.—The question of strict regulations for barber shops has received much attention by sanitarians, but only in a few instances have the health authorities had the moral courage to adopt and enforce rules which must of necessity meet with great opposition and in many instances bring ridicule upon those who promulgated them. In fact, even the medical profession, represented in the American Public Health Association, is not averse to enjoy a little tilt at the expense of one of its members who perennially hammers away at this subject with commendable persistency. Barbers and hair-dressers are public necessities, and the public has a right to insist that their work be performed according to sanitary principles. Any one who patronizes a barber whose establishment is open to all comers runs great risk of becoming infected with diseases from the razor, shaving-brush, scissors, clippers, comb, or hair-brush having been used previously on a sick or convalescent person, especially those suffering from diseases of the skin or scalp. Barbers and

hair-dressers should be required to wash their hands with soap and use a nail-brush immediately after attending to a customer, the razor, clipper or scissors should be dipped in boiling water or a disinfecting solution, while the use of the shaving-brush should be entirely abolished and wads of wool-cotton substituted. To the general practitioner the necessity of such restrictions is self-evident, but the general public needs instruction. Such instruction, however, is slow and ineffective unless obligatory rules are enacted, making it a sort of compulsory education. It is stated by a medical authority, who has made this subject one of his life-objects, that he once treated a man who was covered with specific eruptions, and that the patient went from the doctor's office directly to the barber. As this also happened to be the doctor's barber the lightning struck home.

New Reflexes.—The occupation of discovering new reflexes goes merrily on. Only a few years ago, Babinsky described his curious toe-reflex and the literature on the subject would now fill a respectable volume. More recently still, Gifford, Piltz, and Westphal made many interesting observations upon pupillary phenomena, and at least a dozen articles treating this subject have appeared since the original communication. During the present year, v. Bechterew (*Neurologisches Centralbl.*, March 1, 1900), described a reflex that could be elicited by striking the median edge of the scapula below the external angle. This causes slight adduction and occasionally external rotation of the arm as a result, of course, of contraction of the infraspinatus muscle and perhaps also of the teres minor. Occasionally, the deltoid or the flexors of the forearm are also involved. The center of the reflex according to him is probably about the level of the cervical swelling of the spinal cord. The reflex is remarkable in its constancy. It occurs almost invariably in healthy persons, and therefore its unilateral diminution or complete abolition should be regarded as invariably pathologic. It disappears in cases of the spinal form of progressive muscular atrophy, in polymyelitis, and in neuritis involving the shoulder region, and in the various types of muscular dystrophies, it is weakened or completely abolished according to the intensity of the process. In cases of stiffness of the spinal column (rhyzomelic spondylosis) it is also diminished. It is valuable for the purpose of distinguishing between atrophy of the shoulder muscles due to cerebral and that due to spinal or neural lesions. Two months later, Hanel (*Neurologisches Centralbl.*, May 1, 1900) has been able to report a series of observations that he has carried out upon various persons with special reference to this reflex. He criticises v. Bechterew for not having stated whether the reflex is due to mechanical irritation of the tendons or periosteum. He believes that when the deltoid and biceps are involved, the periosteum

must be irritated, but he thinks it not unlikely that, in general, the twitching is merely due to direct mechanical stimulation of the body of the infraspinatus muscle, particularly as he has frequently been able to observe the so-called idiomuscular tumor when the reflex was unusually pronounced. For this reason the reflex is most readily elicited by striking near the inferior angle of the scapula where the muscle-substance is in considerable quantity. If, however, the inner border of the scapula is struck in such a manner that the muscular substance is not irritated, there is usually no twitching. In 120 cases he found that this reflex was comparatively infrequent, occurring in only 43.4%, while the triceps reflex was present in 80%, and several other reflexes of the upper extremity exceeded the scapulohumeral. He, therefore, does not believe that the latter is of much value in the diagnosis of diseased processes in the region of the upper extremity. He calls particular attention to the fact that in these 60 cases that presented the reflex, 3 showed marked difference between the two sides.

Lithiasis Preputialis.—This exceedingly rare affection is described in a letter to the *Boston Medical and Surgical Journal* (June 21, 1900), by Dr. Albert N. Blodgett. The patient, aged 22 years, had a deposit of stony material beneath the foreskin. There was extreme phimosis of a greatly elongated prepuce. It was impossible to retract the foreskin. The swelling was elongated and the shape of a pear, and the opening was small and directed to one side. The tumor was very hard and unyielding to pressure and was the seat of much pain. A greenish puriform discharge constantly issued from the opening, which was excoriated and painful. No cause could be assigned for the condition. On incision, a perfect collar of a stony material was found surrounding the base of the glans, filling the sulcus, except at the frenum, and prolonged upon the surface of the glans towards the meatus. This calcareous collar was perfect at the time of operation, but was unfortunately broken in removal. The effect of this condition on the mental state of the patient was highly injurious. The young man, who was of neurotic ancestry, had already spent a short time in an asylum for an attack of *folie du doute*, and this anomalous condition of the foreskin threatened to unbalance his reason once more. Dr. Blodgett quotes another and similar case from *La Grèce Médicale* (No. 7, 1899), reported by Dr. Alex. Louis, of Velessa, Macedonia. In this case, which occurred in a married man, aged 45 years, 110 stones were removed from beneath the prepuce. Thirty of these reached the size of a pea, the others diminishing to that of a grapeseed. The condition had lasted seven years, and was marked by great distention of the prepuce, so that this attained a circumference of 25 centimeters. Pain was an acute symptom, and the sense to the touch was that of a bag filled with stones. A sound was readily

introduced beneath the foreskin, where it came in contact with a mass of stones, but these could not be removed without incision of the foreskin, because of the phimosis. A complete cure was obtained. The primary cause of this condition is probably a persistent phimosis, with retention of smegma which undergoes calcareous changes. These preputial calculi, by which term they are generally known in literature, are rare but not unheard of. At least 24 cases are reported according to the *Index Catalogue*.

Crime, Pauperism, and Mental Deficiency.—The great questions involved in the proper disposition and treatment of the criminal; the arrest, if possible, of pauperism; and the care of the mentally deficient are of special interest to the broadminded physician, for it is he who must take the initiative in the proper scientific solution of these problems. As we ascend in the social scale, with the present state of society, especially in the large cities, the number constituting a family becomes smaller and smaller. It requires no mathematician to discover that the shiftless, the thriftless, the indigent poor—the class which produces, relatively, the greatest number of criminals and paupers, if not of the mentally deficient, are increasing out of all proportion to the thrifty, the well-to-do—the class which produces relatively few of the paupers and criminals. How can we account for this disproportionate increase? The sociologist would probably give as the prime cause the growing dislike on the part of parents of the middle and upper classes to be burdened with numerous children. Recent years have added an additional cause, one specially interesting to the physician. We refer to the lavish free-treatment by hospitals, dispensaries, and lying-in institutions to all who apply. Never was such organized and persistent effort put forth to save the weakling, the physically incompetent, those who with less care would perish in the battle for life. This effort at saving life is well, it is our duty; but it has its evil consequences. Parents relieved from much that is onerous in child-rearing are encouraged to beget others of their kind. Thus is beginning a multiplication of the indigent population which threatens serious consequences for the future.

What is to be done with the confirmed criminal, the pauper, the idiot,—the fruits, in too many instances, of this life-saving and life-multiplying process? Our duty to humanity will not allow us to refuse medical aid, but there remains a means under proper circumstances, to prevent the multiplication of certain of these wrecks, these derelicts of humanity. If the confirmed criminal, the pauper, the degenerate—those who have ceased to have a regard for law and the consequences of their own acts—must be supported by the State, then society certainly has the right to say that such at least shall not propagate their kind. It is stated that Michigan has legalized asexual-

ization for certain of these unfortunates. Other States and countries will in time follow her example. To state that a measure like this would affect such a small increase of the population of this baser sort as to be without appreciation, has its partial refutation, at least, in the personal observations of most of us. How many in the course of a lifetime have not seen one or more families composed wholly or in part of degenerates who owe their existence to the want of such a law?

Asexualization will be held by some to be a harsh measure, but it becomes incumbent upon those who would discourage it to offer something better, for the future will compel us to act. Regulation of the marriage law would be ineffectual, because these lower classes have ceased to have respect for the law and the consequences of their own acts.

If society by her philanthropic efforts is forced to annul the law of the survival of the fittest, then self-interest, nay self-preservation, will compel her to adopt measures that will prevent the multiplication of those who at best can only add degeneracy to the race.

Dental Caries.—The report made by the committee appointed by the British Dental Association to investigate and report on the condition of the teeth of school children contains some interesting points. It appears that only about 10% to 13% of school children from 6 to 16 years of age have "sound dentition," i.e. a condition in which no permanent tooth had been attacked by caries at any time. This appears significant, and it would lead to the conclusion that the average child knows little of the toothbrush, and that proper instruction from parents and others whose duty it is to teach along this line has been sadly neglected. For, notwithstanding the influence which heredity, the constitution of the individual, the character of the food, etc., undoubtedly have upon the teeth, surely no one will assert that all these causes combined could cause 90% of growing, and presumably fairly healthy, children to have defective teeth if proper care was observed in keeping them clean. The teeth of poor children were found to be in better condition than those of the well-to-do, and the country-bred child was less liable to dental caries than his cousins in the towns. This is one of the penalties which we pay for getting away from the simplicity of Mother Nature. The Scotch children possessed better teeth than the English. A difference in the habits of the people and in the character of their food probably accounts for this. A study of the skulls and teeth of ancient races did not yield a result so much in favor of primitive man as we might expect; for although their teeth were found much sounder than the average civilized person of today, yet caries was not unknown to them and in some races it was quite marked. The meat-eaters had sounder teeth and better developed jaws than those who lived chiefly on fruit and vegetables. This holds true of the

uncivilized and semicivilized races of the present time. Those races which live upon cooked starches suffer most from dental caries. And yet with respect to the soundness of teeth much seems to depend on the physical constitution and virility of the race.

Dr. W. D. Miller, of Berlin, has shown by careful investigations that the exciting cause of dental caries is lactic acid. Its presence in the mouth causes decalcification of the enamel of the teeth and soon leads to decay. He found that the presence of this acid in the mouth depends largely on the character of the food eaten. With proteids and hydrocarbons no lactic acid is produced in the mouth, but with a carbohydrate food it is produced in abundance unless the mouth is kept free from particles of decomposing food. Here again the demand for the toothbrush and for oral cleanliness is made manifest. It is time the voice of the physician as well as the dentist should be heard in behalf of those measures which conduce to sound teeth; and one wonders whether it were not better that the public school should give more instruction concerning the ordinary care of the teeth, and less attention to the intricacies of digestion.

Infectious Diseases in Hotels Abroad.—The *British Medical Journal* calls attention to the risk of the dissemination of infectious diseases in the large hotels abroad and to the liability and rights of innkeepers in Great Britain and other countries when such cases occur. Sickness is considered an inevitable accident and is one of the risks which the manager of a hotel takes upon himself when he opens his house to the public. The Public Health Act of Great Britain imposes a penalty upon persons who, when suffering from dangerous infectious diseases, expose themselves in any public place, or if guests at a hotel fail to make known their condition. The Act also imposes a penalty upon the proprietor if he rents a house or part of a house which has been occupied by a person suffering from an infectious disease without first thoroughly disinfecting the same. Concealment of disease is also made punishable by a fine.

British law recognizes no implied contract on the part of a guest at a hotel that he is not suffering from an infectious disease, or that, if he should become ill during his stay, he will defray all the cost and make good the damage to the proprietor. It seems from a case reported that a guest cannot be held responsible for the loss occasioned by the suspicion of infection, although he may be compelled to defray the cost of disinfection. In France the law appears to be much the same as in Great Britain and a similar case is reported.

In the large mountain hotels of Switzerland the risk of the introduction and dissemination of infectious diseases has greatly increased during recent years; the hotels are much larger than they formerly were and

many tourists now take their children with them to spend part of the summer, both being factors in the spread of disease. Only last summer in one of these hotels a visitor was stricken with scarlet fever. The hotel, which was both large and well filled, was immediately deserted by all save the unfortunate patient and his friends. The proprietor in this instance behaved with the utmost courtesy and consideration, and was ready to make certain improvements which would enable him in future to secure the complete isolation of any person suffering from infectious disease. It would appear to be to the interest of both proprietor and guests that suspicious cases of illness in these hotels should be at once isolated and treated in a small detached house, since the vacating of a hotel may cause great loss to the proprietor, who will probably be unable to regain public confidence during the remainder of a short season. In any event the tourist will do well to see that his own condition when ill is made known.

The Plague.—The most serious recent report about the plague comes from Glasgow. Passed Assistant Surgeon Thomas sends a cablegram, under date of August 31, to the Surgeon-General of the U. S. Marine-Hospital Service, stating that the Board of Health of that city had declared the city infected with the disease. Eleven cases had been discovered. While this number of cases hardly warrants such an extreme statement as that the city is infected, yet the intelligence is bad enough, and we trust later reports will not add to its ominous character. In Glasgow there should be found as good sanitary ability to cope with the disease as has been exercised in other cities. Thus in Hamburg, Germany, Passed Assistant Surgeon Greene, under date of August 15, reports that seven days had elapsed since the case of plague was isolated in that city and that no further cases had occurred. The case referred to has resulted fatally. Surgeon Greene thinks Hamburg especially well equipped for stamping out an epidemic, as the experience of the sanitary authorities in the cholera epidemic of 1892 has proved most valuable. There has been in various cities, indeed, well-marked and noteworthy success in stamping out the plague. This has been seen in Japan, for instance, where, according to Assistant Surgeon Eldridge, no new cases of the disease had occurred for several weeks prior to August 1, and the authorities in consequence had closed the inspection offices. Dr. Eldridge thinks that this disappearance of plague must be ascribed to the intelligent and energetic measures employed by the sanitary officials of the Japanese Government, as the natural conditions had been favorable for a spread of plague. The recent epidemic in Japan was strictly limited to the city of Osaka and two or three other localities, these epidemic centers being near to and in frequent communication with several large cities; yet not a single

case occurred outside of the centers mentioned that could by any possibility have been derived from the infected area. Dr. Eldridge says in conclusion that considering all the conditions in Japan favorable to the propagation of plague, this success of the authorities in combating the disease proves that the plague must be considered a preventable disease. In Rio de Janeiro, which has the unenviable distinction of having had more plague than any other place in the Western Hemisphere, the disease was quite active during July, and no very marked success seemed to have been attained in controlling it.

Acquired Immunity Against Zymotic Diseases.—Archdall Reid (*Physician and Surgeon*, July 1900) believes that the natural process of recovery or immunization from toxic zymotic diseases is: First the individual is infected by the microorganisms, and is poisoned by their toxins. But if death does not ensue, his cells produce enzymes which digest the toxins, and injure the microorganisms producing them. As digestion proceeds a graduated scale of toxins is produced, and up that graduated scale the cells of the individual react till they become indifferent to the strongest toxins, and are then able to destroy the microorganisms. Pasteur imitated this process in his cure of rabies, and in the production of immunity against anthrax. Jenner did it, all unconsciously, when he procured immunity against smallpox by inoculating with the attenuated virus of vaccinia. Immunization against snake-venom is induced by attenuating the poison in the stomach. It may be possible, on the same lines, to cure a disease by swallowing and digesting the toxins of some disease. On the other hand, all toxins are not digested in the stomach; at any rate they are not rendered innocuous. Opium, or rather morphia, is an example. Were it possible to attenuate morphia by slightly altering its chemical composition, this altered product would probably prove of curative value during actual poisoning with morphia. [M.B.T.]

Treatment for Aortic Aneurysm.—William F. Verdi (*Yale Medical Journal*, January, 1900) reports the result of treatment in 2 cases of aneurysm. The formation of a thrombus is necessary to the cure of an aneurysm of the aorta; and 3 conditions tend to its formation, viz: Lesion of the vessel wall; alteration in the composition of the blood; retardation of the blood-current. The first patient had a large aneurysm of the ascending aorta. It was treated by introducing 20 feet of fine steel wire, and an application of an electric current of 100 milliampere meters strength for 20 minutes. No improvement in the patient's condition was noticed and he died 4 weeks later. The postmortem showed a large fusiform aneurysm, commencing at the beginning of the aorta, with vessel-walls hard, atheromatous and calcareous. The wire was coiled up in the sac, but without the least evidence of a coagulum anywhere. Verdi thinks the rapid blood-current prevented the formation of a clot. The second case was treated by injecting hypodermically, a 2% solution of gelatin in a physiologic salt-solution. The patient was a man, 39 years old, who had developed a slowly growing aneurysm of the arch of the aorta for one year. The second, third and fourth ribs and part of the sternum were eroded. He was first given 50 cc. of a 1% gelatin solution under the skin of the abdomen. After 2 days a second injection of 75 cc. of a 2% solution was used. The pain after the injections was very great and the patient refused to continue after the fifth injection. The patient lived for 3 months, but no improvement seemed to follow the use of the gelatin, though the postmortem showed the walls of the aneurysm covered by older adherent organized coagula. [M.B.T.]

The Fourteenth International Medical Congress will be held in Madrid. Owing to climatic reasons the Congress will meet about Easter, 1903, and will be under the presidency of M. Calleja, Dean of the Faculty of Medicine, with M. Fernández Caro, Inspector-General of the Spanish Navy, as General Secretary.

Reviews.

L'Année Chirurgicale. Revue Encyclopédique de Chirurgie Générale et Spéciale. By DR. A. DE PAGE, of the University of Brussels, Surgeon to the Brussels Hospital, with the collaboration of many eminent surgeons. First volume. Pamphlet form, 672 pages. Bruxelles: Henri Lanertin, Libraire-Editeur, Rue de Marche au Bois, 20. 1900.

With the aid of a very competent corps of assistants Professor De Page undertakes a review of the entire literature of surgery for the past year. The book is divided into three main parts; the first dealing with generalities, such as history, surgical encyclopedias and treatises, a discussion of the use of the x-rays, anesthesia, etc. To this part 136 pages are devoted. The second part deals with subjects connected with the principles of surgery, ulceration, gangrene, embolus, thrombosis, etc.; 139 pages are devoted to this section of the book. The third or greater part takes up the special surgery of various organs. The plan followed is to give first a bibliography of the subject under consideration. The articles are arranged according to the authors' names, in alphabetic order. The title is given in the original followed by a translation in French and a careful reference to the page and volume of the original. After the bibliography comes a review of the various articles noticed, the thoroughness with which the subjects are treated depending upon the importance of the article under consideration. But rarely is more than half a page given to the consideration of any article. The classification under the authors' names has some advantages, and with the division of the book into so many headings it is not very difficult to refer to any subject. However, it would make the work more valuable for reference if there were an index of diseases with cross references. Also in most of the subjects considered everything is bunched together without any attempt at subclassification. For example, in the section on the surgery of the brain and meninges, the discussion of abscess, tumor, hemorrhage, etc., is all given together and in order to refer to any one of these subjects it will be necessary to go through the entire list. The abstracting seems to have been most thoroughly done, and the division space seems judicious for the most part. In doing this work Professor de Page has rendered a great service to all students of surgical literature. We can unqualifiedly commend the book not only to those engaged in research, but to all who desire to find in concise form a review containing the essentials of practically all articles with regard to any subject in which they may be specially interested, which have appeared during the past year. We hope that the work will receive sufficient recognition so that it will be continued.

Clinical Examination of the Urine, and Urinary Diagnosis. A Clinical Guide for the Use of Practitioners and Students of Medicine and Surgery. By J. BERGEN OGDEN, M. D., Instructor in Chemistry, Harvard University Medical School; Assistant in Clinical Pathology, Boston City Hospital; Medical Chemist to the Carney Hospital; Visiting Chemist to the Long Island Hospital, Boston. 416 pages with numerous illustrations and several full-page colored cuts. Philadelphia: W. B. Saunders & Co., 1900.

In addition to the usual contents of a book on urinary analysis the author has added a general discussion of the condition of the urine in the diseases of the kidney and in other general diseases in which the urinary changes are of sufficient importance to merit special attention. The author emphasizes the fact that most of the books on the urine at the present time are devoted almost exclusively to urinary chemistry, and since a knowledge of urinary diagnosis is obtainable only by an extended search through various works on medicine, surgery, and pathology he believes that there is a need for a treatise which takes up in detail urinary diagnosis and the application of information furnished by

careful chemical and microscopical examination. The first part of the book is devoted to a discussion of the chemistry of the urine according to the general plan of the books of this kind. All the usual tests and methods are satisfactorily described, the more important ones being given special attention and the comparative merit of various tests is judiciously discussed. The second part is devoted entirely to the conditions of urine found in various diseases and we believe that the author's idea is an excellent one. In concise form he has collected a great deal of information which will be of the greatest value to the practitioner who would otherwise have to consult numerous authorities in order to obtain the same knowledge. The discussion of the urine in diseases outside of the urinary tract is also a desirable feature which is too often neglected, although highly valuable information may often be obtained in this way. In addition to the two main parts there is an appendix which contains cuts of blanks for recording urinary examinations, a discussion of the order of applying tests and the method of making diagnoses of diseases of the kidneys from the urine; there is also a list of the reagents needed for ordinary work and an excellent index. The author shows that he has studied the literature of his subject most thoroughly and that he has an extensive practical knowledge of his subject. We can heartily commend the book to students and practitioners who are in need of a special treatise on this subject.

A Manual of Operative Surgery. By LEWIS A. STIMSON, B.A., M.D., Surgeon to the New York and Hudson Street Hospitals; Consulting Surgeon to Bellevue, St. John's and Christ's Hospitals; Professor of Surgery of Cornell University; Corresponding Member of the Société de Chirurgie, Paris; and JOHN ROGERS, Jr., B.A., M.D., Surgeon of Gouverneur Hospital, New York; Instructor in Surgery in Cornell University. Fourth revised edition, with 293 illustrations, 614 pages. Philadelphia: Lea Brothers & Co., 1900. Cloth, \$3.75.

In the brief space allotted the author attempts to give a description of general surgical technic and of all usual surgical operations. It may be easily understood that within these limits it is impossible to give extended descriptions. The aim of the book seems to be to give concisely one or two well-established methods without discussing the merits of other possible methods. The book is divided into 7 parts; the first 29 pages being devoted to the accessories of operations; the second part, 30 pages, to ligation of arteries; the third part, 51 pages, to amputations; the fourth part, 90 pages, to the excision of joints and bones; the fifth part to neurotomy, tenotomy, osteotomy and miscellaneous operations; the sixth part to operations on the face and the seventh part to special operations. For the most part the methods selected are satisfactory and the descriptions quite adequate. In these days of specialists it would seem that the chapters on operations on the eye and ear might have well been omitted and the space devoted with advantage to a more thorough description of the other general surgical operations. Some of the methods advocated might scarcely meet the approval of all surgeons; for example, we venture to believe that few would advocate simple ligation of the appendix, excision and treatment of the stump with a cauterizer or pure carbolic acid without any further precautions. This method is described although others are mentioned. In the operations of gastrostomy the excellent methods of Witzel and Kader are described, but the Frank method which is perhaps more generally used at present than any other, is not mentioned. Among the operations for pyloric stenosis, Loreta's operation is given considerable space, a method which is now generally discarded. Among the operations for hemorrhoids, ligation and Whitehead's operation are the only ones mentioned though perhaps more surgeons prefer to use the clamp and cauterizer than any of the other methods. While there may be differences of opinion as to the importance of various methods and the best ways of performing them the book on the whole is very satisfactory. When any book passes through three editions it is sufficient evidence that it has real merits and that it is likely to prove helpful to those interested in the subject discussed.

Manual of Pathology, including Bacteriology, the Technic of Postmortems and Methods of Pathologic Research. By W. M. LATE COPLIN, M.D., Professor of Pathology and Bacteriology, Jefferson Medical College Hospital and to the Philadelphia (Blockley) Hospital; Bacteriologist to the Pennsylvania State Board of Health. Third edition, revised and enlarged. With 330 illustrations and 7 colored plates. Octavo, 846 pages. Philadelphia: P. Blakiston's Son & Co. Price, \$3.50 net.

The task of collecting the results of the observations of others and of selecting those facts which are of greatest value to the student and general practitioner is quite a different one from that of carrying out an independent investigation in pathology or that of writing an exhaustive treatise on the subject. Both tasks are necessary and useful, and in performing the former task the author of this manual has been unusually successful. The book is well arranged, clearly written, freely illustrated and so comprehensive that few points will be found left altogether untouched. The manual will be found especially suited for the needs of the student and general practitioner and in writing the book the author shows the evidence of his extensive teaching experience and knowledge of the practical bearing of the subjects considered.

The manual is divided into three general parts; the first 133 pages are devoted to pathologic technic. The method of performing postmortem examinations is briefly described, bacteriologic technic, histologic methods, and the examination of the urine and sputum are discussed. In the brief space devoted to this section will be found a description of very satisfactory and practical methods of performing all the more necessary manipulations in pathology without any confusing discussion of numerous, complicated methods.

The second part, 156 pages, is devoted to general pathology; hypertrophy, hyperplasia, infiltration and degeneration, necrosis, circulatory disturbances, inflammation and repair, tumors and temperature changes are clearly and concisely treated. The remaining 453 pages, necessarily by far the greater part of the book, is devoted to special pathology. The examination of the blood, the condition of the vascular, respiratory, urinary, digestive, and nervous systems, the bones, joints, muscles, and mucous membranes, serous membranes, etc., each has a chapter devoted to them. The many interesting and valuable original illustrations deserve special mention. The manual is not designed for a book of reference for the skilled pathologist, but as a working manual for the student and for this use it is admirably adapted, as is evidenced by the appearance of this third edition within so short a time after the publication of the first edition of the book.

Epithelioma of the Esophagus Involving the Pneumogastric Nerve.—McKendrick (*Glasgow Medical Journal*, July, 1900), relates a case in which all the symptoms pointed to aneurysm of the aorta and in which, postmortem, an extensive epithelioma of the esophagus was found involving the pneumogastric nerve. The case was that of a woman admitted with symptoms of dyspnea, stridor, cough, and aphonia, with a swelling in the neck the size of a duck's egg. Under the opinion that this was aneurysmal, potassium iodid was given with good results. Following this some dysphagia existed, and symptoms being aggravated by personal worry; pain in the chest was never present, the cough was of a brassy, clanging nature. She died from dyspnea and general weakness. Prior to death there was no sudden onset of symptoms such as might be expected from hemorrhage into the pericardium or respiratory tubes and no change in the physical condition of the heart and lungs. The growth involved the upper part of the esophagus and had the form of an irregularly outlined, sloughing ulcer. On the right side the pneumogastric nerve lost itself in the growth above the clavicle; the recurrent laryngeal branch of the right pneumogastric was also involved in superficial secondary glandular mass, and the left recurrent laryngeal nerve was involved in deeper glandular mass in continuity with the esophageal tumor. Had an esophageal bougie been passed the question of diagnosis would have been cleared up, but McKendrick doubts the justifiability of the procedure. [M.B.T.]

Correspondence.

DISLOCATION OF THE JAW IN HEMIPLEGIA.

By DEWITT C. GREENE, M.D.

of Buffalo, N. Y.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE cases of dislocation of the jaw in epilepsy, reported by Charles J. Aldrich in a recent issue, remind me of a case of dislocation of the jaw following hemiplegia.

Mrs. B., aged 48 years, suffered an attack of hemiplegia with total loss of consciousness; her mind cleared a little and on the fourth day she would answer questions by a nod of the head, but on the sixth day she suffered a second attack, which left her in completely comatose condition, with her jaw dislocated. At first I diagnosed simply a spasm of the muscles; upon a more careful examination I found jaw to be dislocated. As I did not desire to give an anesthetic in her condition I decided to make an attempt at reduction (which I feared however would be futile), by putting the thumbs back between the teeth after having been protected by cloth and following out the technic as laid down in textbooks for reducing dislocation of jaw. To my surprise, after making the second effort at reduction, I could feel the jaw snap back into position, and the teeth came together; but on the tenth day she died.

PNEUMONIA AT HIGH ALTITUDES.

By HENRY W. HOAGLAND, M.D.

of Colorado Springs, Colo.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

COMING recently from the Atlantic Coast, where the prevailing opinion in regard to lobar pneumonia at high altitudes is one of great mortality, I have been surprised at the following cases that have come under my care at St. Francis Hospital. Since the 1st of May we have had 8 cases with no deaths, and in looking up the records of the hospital since January 1st I find 37 cases with 5 deaths—a mortality of but 13%.

The majority of these were men from the mines and railroad-camps on the Colorado Springs and Cripple Creek Railroad; of course they came from a high to a lower altitude, which does influence favorably the course of the disease. But the majority were drinkers and living where the hygienic surroundings were not of the best and exposure to wind and snow more severe than in individual life. Of the cases that came under my care none came in sooner than the third day of the disease. As the treatment was practically the same I will cite but one case, which, however, was migratory in character and the most severe.

J. D., 42 years old, laborer, family and previous history negative, except that he had rightsided pneumonia 8 years ago. He was admitted May 7, the third day of disease, temperature 104 $\frac{3}{4}$ °; respiration 42; pulse 110; physical examination showed consolidation of the base of right lung posterior. Sputum was viscid, "prune juice" in color. On examination pneumococci in great numbers. Patient was sponged and temperature fell to 102.6°, where it ranged from 102° to 103.6°. Pulse never over 140, nor respiration over 52. On the morning of the ninth day temperature fell to 97.6° and the patient slept, but the respiration remained high. That afternoon he had a chill, and the temperature rose to 105°, respiration 52, pulse 140. The sputum again assumed the prune juice color, but where the pneumococcus was in abundance the first involvement the second showed streptococci in abundance. The following day a consolidation developed in the upper lobe anteriorly of the left lung. This attack lasted five days, followed by a rapid lysis. Patient made a slow but complete recovery.

While I believe at altitudes higher than the neighborhood of 6,000 feet pneumonia is more fatal even in those acclimated, in my experience I am inclined to believe that while pneumonia is pneumonia everywhere and as such is to be dreaded, it is no more fatal in altitudes as high as Colorado Springs than at sea level.

A SIMPLE METHOD OF REDUCING LUXATIONS OF THE SHOULDER.

By THOMAS M. PAUL, M.D.,

Assistant Surgeon, State Hospital, Hazleton, Pa.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE method invariably pursued in treating recent luxations of the shoulder-joint at this institution is as follows:

The patient is chloroformed; practical experience with this drug having taught us that its use is not attended by the dangers usually ascribed to it, and it produces greater relaxation of the muscles. The arm is held at a right angle with the body and drawn straight outward with one hand at the wrist, while the finger tips of the other slip the head of the bone into its socket by simply pushing it upwards.

Occasionally this is unsuccessful. The method is then slightly modified by using the finger tips on the head of the bone as a fulcrum, while downward lever-like motions are made with the arm; the upward pressure of the finger-tips and outward traction on the arm being meanwhile continued.

The above description applies to the subglenoid variety of the injury, but it may be easily further modified by any intelligent surgeon to suit the exigencies of the case.

This method is, as far as I know, entirely original with Dr. Lathrop. It may be claimed by some surgeons that it is simply manipulation and only applicable to certain cases, but Dr. Lathrop, during a large experience with this traumatism, has never known this procedure to fail.

Cases have been brought to this hospital which resisted every effort at reduction, and in which so much force had been used as to cause great contusion of the superficial tissues of the shoulder and axilla, and yet the above method produced the desired result with the same degree of ease as is expressed by its description.

DOES LIFE IN THE PHILIPPINES PRODUCE A SPECIES OF INSANITY DUE TO PHYSICAL DISTRESS?

By ARTHUR T. ABERNETHY, PH.D.,

of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

IN the PHILADELPHIA MEDICAL JOURNAL, April 7, there appeared from the pen of Dr. Charles E. Woodruff, assistant surgeon of the U. S. Army, one of the most interesting contributions upon life in the Philippines that has ever been given to the American student. Not only the practical physician, skilled to appreciate the technical and professional learning shown in that article, but as well the layman must have read that contribution with the deepest interest. The recent appearance of the news-item announcing the illness of the redoubtable Captain Coghlan, of the *Raleigh*, recalls to mind a discussion along the line indicated in Dr. Woodruff's article which may interest the medical profession. Does this tropical life—especially such as is experienced by the sailor soldier—produce a kind of mental disorder, which

I should term Philippine insanity? There is no questioning the fact that whatever may be the claims set by enthusiastic space-writers in Sunday magazines, mere military life, even at sea, will not produce the physical and thereby consequent mental distresses which have been painfully numerous in the lives of our soldiers in the Philippines; for the observer must have noted in the reports from the Santiago campaign that there has been little or, indeed, no complaint upon these grounds, while among our army and navy representatives who have been identified with the Philippine campaigns there has been an abundance of material to compel an entertainment of a strong belief in the theory advanced. Having known Lieutenant Hobson for years—indeed since boyhood—I noticed a particular and marked improvement in his physical and mental constitution after his return from the naval duties of the Santiago campaign. From a weak, almost unhealthy, lad of angular proportions, he looked, when in Philadelphia at the Peace Jubilee, just subsequent to his return to the United States, like an athlete trained for an international contest. I was with him in his rooms at the Walton when he was dressing for the parade, and saw him stripped to the waist. This physical improvement, indeed, could have been traced in all the participants in the Santiago campaign, barring, of course, occasions when physical debaucheries interfered with natural growth and development.

But the returning heroes of the Philippines have shown a remarkable tendency toward insanity, physical distress, and general breakdown.

Dr. Woodruff says, in his article in the PHILADELPHIA MEDICAL JOURNAL: "Everywhere we hear of some means taken to avoid exhaustion. It is the country of *manana*. The symptoms of exhaustion are everywhere. I never heard so many complaints of persistent insomnia as I did in the Philippines. *One young, vigorous staff officer complained to me one day that on the previous afternoon at 5 o'clock he found that he could not remember anything he read. When he got to the end of a sentence he had forgotten the beginning. He was completely disabled until the next morning. A surgeon informed me that before he was half through his rounds he daily discovered that he could not remember the patients' answers, and he always had to lie down 30 to 60 minutes before the brain would again work properly. It was rumored that a general officer one day at an early hour found himself in the same condition, he could act on no papers because he could not remember what was to be acted on.*" Further on Dr. Woodruff says: "A very high percentage of soldiers have gone insane."

Continuing, Dr. Woodruff tells us that "the children of Europeans reared in Manila and the Philippines become thin, sallow, unhealthy, and that it is an impossibility to rear a third or fourth generation of these races. He declares that in Manila he saw no healthy white children at all, and that the average life of a white child in that section is only 25 years and rarely that. He says, continuing: "The higher intellectual life is lost, is impossible in fact, . . . the heat paralyzes the will, and though men live, they live somewhat like vegetables. *Mental deterioration is inevitable under such conditions. . . . If there is one thing then that medical science can prove, it is the deterioration of white men in a continued moist heat (referring to the Philippines).*" When we consider the fact that the Mediterranean races furnish in our slums the largest proportion of rickets and other diseases due to degeneration, and that the Spanish nation is at present confessedly the most degenerate in Europe, we can well believe the claim laid by the writer that a prolonged stay in the

Philippines is disastrous to the physical and thereby mental condition of Americans.

Another and seemingly convincing argument favoring my assertion that the brain power and the brain activity are dwarfed by this tropical life is the comparative difference between the sizes of the brains of people living in the tropical sections and the colder countries like the United States—its northern and northwestern portion. The tables of Dr. Joseph Sims, published in *Popular Science Monthly*, and to which reference is made by Dr. Woodruff, show that while the capacity in cubic inches of the brains of the Lapps and Swedes is over 100, and that of the Americans 94, that of the Egyptians, Fellahs, and Bengalese is below 78 at their very highest. All of which shows that the warmer the climate the smaller the development of the brain. When we consider, too, that, notwithstanding the general belief, more ingenuity and brain work is required to earn a living in a savage country where there are no mills, factories, nor machinery to afford routine work and where every man must be a hunter, artisan, or soldier—and thus there is a kind of mental development even among savages that must not be forgotten in this computation—we are able to see the bearing these statistics have upon the case in question. Dr. Dawalt, at one time, I think, the Coroner of San Francisco, and one of the prominent physicians who went to Manila to study the Filipinos, declares that their minds are so dulled to the existing state of their feelings that they would frequently come to him for bandages for mortal wounds and would tear them off and expose the wounds to the sunshine and heat as soon as they were bandaged—and apparently without the slightest sensibility to the awful pain.

Now, it is reasonable to suppose that physical distresses of such magnitude must naturally drain and strain the brain power and impair it perhaps seriously. It requires no medical skill to see that intense heat is destructive to clear reasoning, and disturbs mental activity. This distress draws upon the vital currents of the brain, and will in time completely outwear them. If men may eat, drink or do things which impair the mind, it is equally as reasonable to suppose that they may do things that will improve the brain, and vice versa, and it naturally follows that these continuous tropical adventures will produce a mental exhaustion followed by mental wreckage and some sort of dementia. I do not maintain that this is always of a violent nature—insanity is not always confined to a delirium and dangerous classification. But I believe the facts show that a few years' stay in the Philippines almost invariably damage the mental activity of those who go there. In many of our men, this mania assumed suicidal tendencies. I learn that in one month 39 officers and men of rank in the army committed suicide in the Philippines. As previously stated, hundreds—probably thousands if we could know the facts—have become violently insane. Hundreds became dazed and groped about like blind men. Many more were overtaken even after their return to America by complete physical and mental exhaustion in a form milder because of the bracing American climatic influences, and died of influenza, or after complaints that under ordinary circumstances would not have indisposed them.

Captain Gridley, of the *Olympia*, died before returning to the United States. Flag Lieutenant Brumby, Dewey's bosom companion at Manila, died only a short time after his return to this country.

Lieutenant Hobson, who gained over 50 pounds weight in the naval service, and was the hale and healthy man of the Santiago campaign, was sent to the Philippines, where, although accustomed to naval service in every sort of climate, he suddenly collapsed and he is now confined to a hospital in the Orient for treatment for physical disturbances of a serious nature. I recall, too, in conclusion, the pathetic suicide of Commander McGiffen, who took part in the Yalu River engagement of September 17, 1894, near this section. He returned to America, and after 3 years' effort to overcome the effects of the climate wreckage, he shot himself to death in the Post-Graduate Hospital of New York.

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Diphtheria in Camden.—An epidemic of diphtheria threatens Camden, N. J. Recently 12 cases have been reported.

Pennsylvania Military College.—Dr. William B. Ulrich, of Chester, has resigned as chief surgeon of the Pennsylvania Military College, after nearly 30 years of service.

Guard Against Plague.—The steamship *Corean*, which is now due at Philadelphia from Glasgow, will probably be held in quarantine for several days on account of the bubonic plague raging in that city.

The Children's Hospital and Dispensary in Germantown was dedicated and formally opened recently. At present there is accommodation for 25 patients, but the Board hopes to double that number in the near future.

Impure Water at Mount Holly.—The water now used at Mount Holly, Pa., is said to be unfit to drink and the company organized some time ago is considering the question of establishing a new water system, the supply to come from artesian wells.

Boys Drank Pint of Whisky.—Two drunken lads, aged 11 and 12 years respectively, were recently taken to the Pennsylvania Hospital in the patrol wagon. They said two other boys had given them a pint of whisky, all of which they drank.

Typhoid Fever. No Physician.—Surrounded by faith curists, Miss Amelia Pearce, of New Castle, Pa., died recently of typhoid fever at the Alliance Home. She had been ill for 2 weeks, and, it is said, no physician was called. The coroner is investigating the case.

Sanatorium at Red Bank.—The present season's work of the Sanitarium Association, of Philadelphia, is drawing towards its close. For the 65 working days since the opening of the Sanitarium to date the total number of admissions is 163,102, an average of 2,509 daily. The hospital cared for 73 cases.

Dangers of an Epidemic.—Through the neglect of the Bureau of Health of Philadelphia, to quarantine a house near Broad and Annin streets, the neighborhood is in danger of an epidemic of diphtheria. For 15 hours a child who had died of diphtheria was allowed to lie by an open window and 5 other children allowed to remain in the house. The attending physician claims to have promptly notified the Bureau.

Dust Plants Inspected.—Dr. J. Howard Taylor, of the Philadelphia Board of Health, recently inspected the concerns of the Alcatraz Paving Companies which have been declared a nuisance on account of the dust. The Board of Health has yet to take action in the matter. Resolutions adopted over 6 weeks ago condemned the dust nuisance and ordered the health officer to close the plants if the nuisance was not abated. Whatever is done will be the consequence of Dr. Taylor's report.

Association of Hospital Superintendents.—The second annual convention of the Association of Hospital Superintendents was held in Pittsburg, Pa., August 21-23, at Hotel Schenley. An interesting paper was read by T. Sutton, of Detroit, on the growth and development of hospitals in the United States during the past 3 years. He stated that in the last 3 years about \$245,000,000 had been spent in the United States in the erection and equipment of new hospitals, in enlarging and improving old hospitals and in general expenses. Over 1,000 hospitals were built during that time, the approximate cost of which was \$50,000,000. There are now about 65,000 persons employed in the 2,500 hospitals and asylums in the United States. The hospitals pay yearly in salaries about \$23,332,000. Over 1,600,000 patients are treated every year and 37,500 physicians attend them. The following papers were also read: "Hospitals and Dispensaries," by J. S.

Knowles, of Cleveland; "Some Responsibilities of a Superintendent," by C. S. Howell, of Pittsburg; "Hospital Sanitation and Ventilation," by Lewis R. Curtis, of Chicago, and "Civil Service as Applied to Municipal Hospitals," by Dr. Duryea. The membership is now about 100. Charles S. Howell, of Pittsburg, was elected chairman for the ensuing year. The next meeting will be held in New York.

Vital Statistics of Philadelphia for the week ended September 1, 1900:

Total mortality		413
Disease.	Cases.	Deaths.
Inflammation of appendix 2, brain 8, bronchi 1, kidneys 15, heart 1, lungs 19, pericardium 3, peritoneum 4, stomach and bowels 17, spine 3		73
Tuberculosis of lungs		49
Cholera infantum 42, morbus 1		43
Marasmus 24, inanition 9, debility 5		38
Heart—disease of 30, dropsy of 1, fatty degeneration of 3		34
Carcinoma of bladder 1, face 1, liver 2, cecum 1, omentum 1, prostate 1, rectum 1, stomach 5, uterus 4, lymphadenoma 1		18
Bright's disease 4, uremia 7, diabetes 5		16
Apoplexy 11, paralysis 5		16
Diphtheria	61	13
Casualties		12
Convulsions		10
Typhoid fever	60	8
Brain—congestion of 4, disease of 1, dropsy of 1, softening of 1		7
Sunstroke		7
Old age		6
Drowned		5
Burns and scalds		5
Obstruction of bowels		5
Alcoholism		4
Cyanosis		4
Diarrhea 2, dysentery 2		4
Scarlet fever	20	3
Septicemia		3
Jaundice		3
Childbirth		3
Whooping-cough 2, gunshot wounds 1, ulceration of rectum 1, tetanus 1, teething 1, suicide—arsenic 1, laudanum 1, electric shock 2, retention of urine 1, leukemia 1, hernia 1, hemorrhage from stomach 2, uterus 1, fistula 1, epilepsy 1, croup 1, cirrhosis of liver 1, carbuncle 1, anemia 1, asthma 1, psoas abscess 1		

NEW YORK.

The Cornell Medical College is now nearly completed. It has cost, including the site, more than \$600,000.

Sues for Damages.—Dr. Justin Herold, of New York, has brought suit for \$100,000 damages against the Metropolitan Street Railway Company for injuries received in a collision.

Vessels from Glasgow Detained.—Since August 31, all vessels arriving in New York from Glasgow have been detained and will be for a period of 12 days from their embarkation on account of the plague in that city.

Hydrophobia in New York.—Edward Peterson, who died recently in the Harlem Hospital from hydrophobia, was the seventeenth case in New York City in 5 years. The disease reached its climax in 17 days, an unusually short period.

To Isolate Tuberculous Patients.—In February, 1901, the hospital on Blackwell's Island, New York City, will be relieved of its insane patients, who will be apportioned among the different State hospitals near the city. This will then be made a general isolation hospital for cases of tuberculosis under the care of the Department of Charities.

The Home for the Friendless of Northern New York is an institution in Plattsburg which has been maintained and conducted for 25 years by the women of that place. It is one of the most practical and successfully conducted institutions in the State. The inmates are all children—deserted or destitute—for whom good homes are found, if possible, and if not they are carefully trained in the Home.

Moving Pictures.—One hospital in New York has adopted a camera to record minutely the action of patients, and many moving pictures have been taken, showing the movement in walking of persons afflicted with locomotor ataxia. They are produced slowly on the screen, so that physicians are enabled to study the symptoms carefully.

NEW ENGLAND.

Newton Hospital.—Plans have been drawn for an entirely new structure to take the place of the contagious department of the Newton Hospital at Newton Lower Falls, Mass., which was partly destroyed by fire last May. The new building is planned for 52 patients.

Contract and Association Physicians.—Dr. W. O. Dunham, of Springfield, Mass., was recently prevented from caring for a patient of his, suffering from typhoid, after his removal to Mercy Hospital. The staff physicians are members of the local medical association and are therefore arrayed against the 4 physicians who are outside the association and are doing work for societies at "contract" prices. The question of who will be allowed to practise in the hospital is determined entirely by the staff physician.

CHICAGO AND WESTERN STATES.

Scarlet fever is spreading in the eastern portion of the city of La Crosse, Wis. The cases thus far have been mild.

A Low Death-Rate.—Milwaukee's death-rate, as shown by the late U. S. Census report, is 14.27%; that of Chicago 16.56%.

Fined for Selling Putrid Food.—W. E. Gilbert, of St. Joseph, Mo., was fined \$50 recently for selling impure and putrid food to the poor, many of whom were made dangerously ill.

The Rocky Mountain Interstate Medical Association, at its recent session in Butte, Montana, selected Denver, Colo., as the next meeting-place, in September, 1901. Dr. C. R. Fleming, of Denver, was elected president.

University of Illinois.—Dr. George P. Dreyer, of Johns Hopkins, has been elected professor in charge of the physiologic department of the College of Physicians and Surgeons, the medical department of the University of Illinois, Chicago.

Health Department's Demands Refused.—The Board of Health of San Francisco recently presented 6 demands, aggregating \$700, which they desired to be paid out of the appropriation set aside for emergencies in the small-pox hospital. Auditor Wells refused to audit the demands on the ground that the fund of \$4,000 is intended only for an epidemic, should one ever occur.

Medical School to be Established in Dallas.—At a recent meeting of physicians in Dallas, Texas, it was proposed to establish a medical school in that city. The majority of those present voted against the proposition. However, a number of those present held a supplementary meeting after the adjournment of the regular meeting, and committees were appointed to formulate plans for the establishment of a school.

Poisoned by Ice-cream.—The Odd Fellows of Glendale, Ind., held their annual reunion festival recently, and shortly after ice-cream had been served, more than 100 persons showed symptoms of poisoning. Every physician in the vicinity was summoned, and the I. O. O. F. hall was transformed into a temporary hospital. The sufferers were soon got out of danger. It is supposed that the cream was frozen in cans which had not been well cleaned.

Indians Dance for Charity.—The Winnebagoes near Black River Falls, Wis., began the medicine and "give-away" dance. Food, clothing, and money were donated to the aged and helpless members of the tribe. The dance is an old custom among the tribe, and while not so well as the charity ball in the big cities, the motive is the same. A young Indian who wishes to shine in society will beggar himself, in order to be generous during the excitement of the dance.

Charity Hospital for Albuquerque.—The Mayor of Albuquerque, N. M., has received a letter from the mother superior of the Order of the Sisters of Charity, Cincinnati, O., stating that the proposition made by the City of Albuquerque to them for a hospital and sanatorium had been accepted, and that they would commence work on the institution in September. The citizens of Albuquerque have presented the order with \$5000 toward the institution, and ground was given to them by Father Gentile.

To Prevent Spread of Tuberculosis.—In his annual report to the common council Health Commissioner Schultz, of Milwaukee, recommends legislation that will control marriages and thus lessen the ravages of tuberculosis. For the same reason he recommends the examination of teachers applying for positions in public schools. The report also states that wells are a positive menace to the welfare of the community. Out of 118 examined by the department, the water in but 16 was fit to use. There were 1,100 cases of scarlet fever in the city in 1899, with but 36 deaths from that disease, and 722 cases of diphtheria with 109 deaths, the lowest percentage of fatalities since 1891.

A Business Association Formed by Detroit Physicians.—A "Physicians' Business Association" has been formed in Detroit to promote professional and fraternal goodwill; to correct the abuse which the profession has long suffered through nonpayment of legitimate fees; to agree upon a uniform fee bill, and to regulate the relations of the members to each other and to the public hospitals, dispensaries and public charities. It is also purposed to found a mutual aid fund for members in full standing. The affairs of the association are to be conducted by the officers and a board of governors, which will be composed of one representative from each ward of the city, each governor to be elected by the physicians residing within the ward which he represents. Should any physician decline to join the organization after being duly solicited the members will be forbidden to consult with the offender. It is proposed to circulate each month among the members of the association, a printed "black list" of persons who refuse to pay their physician's bill. It is reported that nearly 400 signatures to the call for organization have already been secured. A preliminary meeting which was held at the Hotel Cadillac was presided over by Dr. J. J. Mulheron.—[*New York Medical Journal*]

A Journalistic Reform.—The publisher of the *Brown County Herald*, of Hiawatha, Kansas, has this to say of medical advertising and advertisers: "We have at last done what we have wanted to do for many years—we have thrown out of this paper every advertisement that can be by any chance considered objectionable in any degree. And hereafter we shall print no offensive advertisements. We have an idea that every advertisement is read, and this being so, we don't want any one to read or to put any faith in the cure-alls and nasty nostrums that are always conspicuous advertisements in every possible newspaper and in every possible public place in America. If persons are ailing, they should not hesitate to consult a reputable physician. Another thing: From this time on we will not print advertisements of traveling quack doctors. We want clean advertising matter, or else we want none. This means a loss to us of not less than \$800 a year. We believe that the people who have glanced at Lydia Redham's offensive propositions, and at Slow's Specific, Bradshaw's Regulator, et al., including the bids of various quack doctors to cure weak and suffering men and women, will miss them in this paper with not a little pleasure. It makes no difference what ails you, don't be afraid to tell an honorable physician about it, and submit to his advice and treatment. Beware of quack doctors. Don't read filthy ads. Don't buy quack medicines. Don't have anything to do with strange doctors. They are generally disreputable, and entirely unable to do any more for you than to mercilessly take your money."

SOUTHERN STATES.

From a Bubonic Port.—On the way to Baltimore is the steamer *Orithia*, which sailed from Glasgow about the time the bubonic trouble had developed. Dr. Heiskell will take charge of the vessel upon her arrival and detain her for a period if he thinks it necessary.

Maryland General Hospital.—The clinical amphitheater at the Maryland General Hospital, Baltimore, and the two operating rooms are being improved.

Baltimore University School of Medicine.—Dr. Benjamin S. Hayden has been elected to the chair of materia medica and therapeutics in place of Dr. E. Eilau resigned.

Clarence Barker Hospital.—George W. Vanderbilt has started an endowment fund for the Clarence Barker memorial hospital at Baltimore, N. C. The hospital was formally opened September 4.

Yellow Fever on Steamer.—The German fruit steamer *Holstein* has arrived in quarantine at Old Point, Va. The mate in command reported that Capt. Arhoos died of yellow fever and was buried at sea. The Marine Hospital surgeons have boarded the *Holstein*. It is reported that others of the crew are down with yellow fever.

Experiments with a Weed.—The faculty of the Chattanooga Medical College is making experiments with the weed known as "gall of the earth," with which a mountaineer lately cured himself of a mad-dog bite, and by which he cured others of the effect of the venom of poisonous snakes. In some places it is known as the "rattlesnake master." Quantities of the weed are being transplanted for cultivation and experiment. It is now in bloom and bears a small white flower. The horticultural department of Clemson College, at Charleston, S. C., is experimenting with it also.

New Orleans Isolation Hospital.—The Board of Health of New Orleans recommends that, should an isolation hospital be built, the institution be under the immediate supervision of the Board of Health; that the physician in charge be of the board's selection, and removable for cause by the board; that his services be utilized in other directions by the board in the absence of any infectious disease; that his salary be fixed and budgeted for by the city, and that all other expenses attached to the operation of the hospital be met by the city, on the approved vouchers of the Board of Health. The board further recommends that the hospital should be centrally located and that it should be on the pavilion plan.

Orleans Parish Medical Society.—At a meeting, held August 11, 1900, Dr. S. L. THEARD submitted diagrams and plans for the proposed isolation hospital to be erected in New Orleans in the near future. Dr. O. L. POTHIER read on the **Pathology of the kidney.**

At the meeting of August 25, Dr. L. G. LEBEUF read on **Medical diseases of the kidney.** DR. RUDOLPH MATAS made a lengthy report of a case of **Aneurysm of the aorta near the celiac axis, treated by wiring and electrolysis.** The patient was a white male, 23 years of age, in whose history there could be found nothing to account for the presence of the aneurysm. Absolute rest in bed with low diet was tried, but failed to benefit the case. Gelatin was injected once, but the febrile reaction and systemic disturbance was so great it was not repeated. An exploratory laparotomy was done, the relations of the neighboring viscera to the tumor determined, and the peritoneum of the anterior abdominal wall stitched to that covering the aneurysmal sac in such a manner as to wall off a small area from the general peritoneal cavity during further operative treatment. Wiring and electrolysis having finally been determined upon, about 10 feet of a specially prepared coil of silver wire was introduced into the aneurysmal sac and electrolysis maintained for a space of over 4 hours, occasioning the patient but little pain or discomfort. The tumor shrunk in front, but a diverticulum formed on the left posterior side and terminated the case fatally in a few days.

Dr. E. J. HUNTER exhibited drawings of a **specially devised brace for correcting talipes calcaneus**, reporting the case in connection.

MISCELLANY.

A Chilean Medical Congress is announced for December of the present year.

Plague in South America.—A case of bubonic plague has been officially reported at Buenos Ayres and another at Rio Janeiro. Several cases have been reported at Ceara.

Sick Soldiers from Manila.—The United States transport *Thomas* arrived recently at San Francisco, 29 days from Manila, via Yokohama. She has on board 261 sick and wounded soldiers. During the voyage 7 deaths occurred.

University of Havana.—Dr. John Guiteras, who resigned the chair of pathology in the University of Pennsylvania to fill a similar position in the University of Havana, has established there a journal, entitled *Revista de Medicina Tropical*.

Yellow Fever Suspect on Havana Liner.—Ignacio Garcia, a steerage passenger on the *Leon XIII*, which arrived in New York recently from Havana, was removed to Swinburne Island for treatment and observation. Garcia shows symptoms indicating yellow fever. The steamer and 124 passengers are held at Quarantine.

Soldiers Leave Hospital.—From the General Hospital at the Presidio, San Francisco, 31 soldiers, fever stricken or wounded in the Philippines, were discharged recently and given transportation to Washington, D. C. Most of the complaints are incurable, and the men have applied for admission to the Soldiers' Home at Washington.

Foreign Physician Accused by Medical Society.—An agent of the County Medical Society charged Louis Capobianca, of New York, with practicing medicine without being registered. The defendant asserted that he received his diploma in Italy, and did not know that he would have to register in this country. He was held for trial.

"Lawton" to Relieve Miners.—The United States transport *Lawton* is to be sent to Cape Nome to relieve the destitute miners, many of whom have petitioned through General Randall for transportation south before the hard Alaska winter sets in. The *Lawton* will sail for the North as soon as she can be got ready, probably within a few days. She has accommodations for about 700 men.

Disease Decimates Eskimos.—Mr. Jackson, the Interior Department representative in Northern waters, reports that grip, pneumonia and measles have been epidemic all summer among the Eskimos. The ravages extended from the Aleutian Islands to Point Barrow. Out of a population of 400, on the Island of St. Lawrence, 36 Eskimos died. The revenue cutter *Bear* was loaded with supplies, and sent to the relief of the natives.

One Thousand Dollars from Red Cross Auxiliary.—Surgeon-General Van Reypen, United States Navy, has received, through Mrs. Whitelaw Reid and Mrs. W. S. Cowles of the Red Cross Auxiliary No. 3, a check for \$1,000 for the relief of the sick or wounded sailors, marines, and soldiers in China. He has cabled \$500 to the fleet surgeon of the Asiatic Station and \$500 to the medical officer in charge of the United States Naval Hospital at Yokohama, to be used in accordance with the wishes of the donors.

No Base Hospital for China.—The large base hospital which the U. S. Government proposed to build at Nagasaki, Japan, has been abandoned since it is probable that our troops may soon be recalled. Our sick and wounded soldiers will be brought from China to the general hospital at the Presidio, San Francisco. The physicians and nurses who had been ordered to Nagasaki will remain in San Francisco until it is definitely decided that their services will not be required in China or the Philippines.

Ambulance Corps Praised.—A Japanese correspondent with the allied forces sent the following to his paper after the battle of Tien Tsin: "The American ambulance corps has done some excellent work. Their stretchers are the best in the field and show the wonderful inventive faculty of the Americans. The handles of these stretchers are so arranged that they can be formed at once into supports by a clever mechanical contrivance, so that these stretchers can be used as beds or benches for surgical operations. The advantage of this system cannot be too much commended, for on ground so swampy and hot as the soil of China the wounded men cannot safely lie long pending the treatment on the spot; and this inconvenience is removed by the American invention. Sixty men were thus treated directly where they fell who otherwise would have died. The Japanese medical staff refer to the fact in most praiseworthy terms."—[*Army and Navy Register.*]

Object to Vaccination.—Owing to the unusually heavy westward passenger traffic, many American citizens have recently been compelled to take steerage passage in returning to the United States. The physicians of the North German Lloyd Steamship Company have insisted on vaccinating all these, to meet the requirements of the United States laws. Recently an American filed strong objections with the United States Consul at Bremen, who wrote to Washington for instructions, meanwhile forbidding the physicians in question to vaccinate Americans in the steerage, on the ground that the law was intended to apply to immigrants only.

Yellow Fever in Havana.—The chief quarantine officer in Cuba reports 204 cases and 34 deaths from yellow fever in Havana from August 1 to 26. The disease is very mild, and for this reason the various quarantine stations on the Atlantic and Gulf Coasts have been instructed to use particular care to detect such cases. The outbreak is confined to a large extent to the Spanish colony. The best quarters of the city are affected, the lower portions being almost exempt. The authorities contend that cleanliness is of no effect in preventing the contagion, and local conditions seem to substantiate this. At present 85 cases are under observation.

Smallpox.—The spread of smallpox continues throughout most of the States. Up to the present time there have been reported 3,346 cases of this disease as compared with 805 cases reported during the same period of time in 1899. The increase is particularly notable in Alaska, Colorado, Indiana, Louisiana, Minnesota, Texas, North Carolina and Ohio. These last two States show a marked increase. In North Carolina, from May 1 to June 30, 440 cases were reported, as contrasted with 68 during the same period of 1899, while during the first 6 months of 1900 Ohio has reported 1,353 cases, contrasted with a total of 20 cases for 1899 during the corresponding months.—[*Medical News.*]

Obituary.—FERDINAND E. CHATARD, of Baltimore, Md., August 27, aged 61.—R. L. MAYFIELD, of Water Valley, Miss., August 28.—FRANK STEPHEN MILBURY, of Brooklyn, N. Y., August 29, aged 44.—ISAAC C. DETWEILER, of Reading, Pa., August 29, aged 70.—JOSIAH S. BOWEN, of Mount Washington, Md., August 29, aged 69.—WILLIAM R. AMICK, of Scipio, Ind., August 29, aged 50.—J. TRAVIS TAYLOR, of Richmond, Va., August 31, aged 26.—WILLIAM S. WARD, of Newark, N. J., September 1, aged 79.—J. A. GORE, of St. Joseph, Mo., August 30.—J. K. McLEOD, of Moss Point, Miss., August 30, aged 60.—FREDERICK HENRY DUPERIER, of New Iberia, La., August 18, aged 67.—WILLIAM BOYCE, of Auburn, N. Y., August 17, aged 67.—A. W. GRIGGS, of West Point, Ga., August 16, aged 72.—CHARLES W. PARSONS, of Louisville, Ky., August 18, aged 68.—JAMES H. ROBBINS, of Hingham, Mass., August 22, aged 60.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended August 31, 1900:

SMALLPOX—UNITED STATES.

Changes in the Medical Corps of the U. S. Army for the week ended September 1, 1900:

McHENRY, G. A., acting assistant surgeon, now at Holguin, Cuba, will proceed to Santiago, Cuba, for duty at the yellow fever hospital.

COONEY, DANIEL C., acting assistant surgeon, will proceed to the headquarters of Second Artillery, Vedado, Havana, Cuba, and report to the commanding officer, artillery defenses of Havana, for duty at that place.

WHEATE, J. M., acting assistant surgeon, is relieved from duty at Santa Clara, Cuba, and will proceed to Rowell Barracks, Cuba, for duty.

ARTHUR, Major Wm. H., surgeon, will proceed on the army transport "Warren" for duty in China.

CALDWELL, ROBERT E., acting assistant surgeon, is assigned to duty on the transport "Rosecrans."

MAZZURI, PAUL, acting assistant surgeon, is granted leave for one month, with permission to go beyond the limits of the division of Cuba.

IVES, Major FRANCIS J., surgeon, will stand relieved from temporary duty in San Francisco, Cal., on the day of the sailing of the transport "Warren," and will on that day assume command of the hospital corps detachment ordered to sail on that ship, and proceed with the detachment to Nagasaki, Japan. Upon arrival at Nagasaki Major Ives will proceed with troops to China, reporting upon arrival to the commanding general U. S. forces, for instructions.

USHER, First Lieutenant FRANCIS M. C., assistant surgeon, is relieved from temporary duty at the Army general hospital, Presidio, and will report to the commanding officer, Third Battalion, Fifth Infantry, in camp at that station, for duty with that battalion.

LOWER, WILLIAM E., acting assistant surgeon, now at the Army general hospital, Presidio, is assigned to temporary duty with troops on the Army transport "Warren," to sail about August 16. Upon arrival at Taku, China, Surgeon Lower will report to the commanding general, U. S. forces in China, for assignment to duty.

POPE, Lieutenant-Colonel BENJAMIN F., deputy surgeon-general, is relieved from temporary duty in San Francisco Cal., and will proceed to the Presidio for duty, to relieve Major Philip F. Harvey, surgeon.

HARVEY, Major PHILIP F., surgeon, will proceed to Nagasaki, Japan, on the Army transport "Sherman," to sail about August 20, to establish a base hospital at that place.

CONEGYS, Major EDWARD T., surgeon, will proceed on the Army transport "Sherman," to sail about August 20, to Nagasaki, Japan, for duty as medical supply officer at that place.

The following named acting assistant surgeons, now at the stations designated, will proceed on the mail steamer "Gaelic," to Nagasaki, Japan, and, in event that there is no Army transport sailing at once from Nagasaki for Manila, P. I., the medical officers named will continue the voyage to Hong Kong, China, on the "Gaelic," and thence by mail steamer to Manila, where upon arrival they will report for assignment to duty: ALBERT W. DENN, DAVID W. OVERTON, JAMES W. THORNTON, FREDERICK A. DALE, GRAHAM E. HENSON, JAMES KENAN, LOUIS W. PEASE, HARPER PEDDICORD, THORNTON W. PERKINS, and FRANCIS M. WELLS, Army general hospital, Presidio; JOHN M. FEENEY, and JOSEPH PINQUARD, Presidio.

The following named acting assistant surgeons, now at stations designated, are assigned to temporary duty with troops on the

Army transport "Sherman," to sail about August 20: GEO. B. WALLACE, LEWIS P. BLEASEBY, JAMES F. EDWARDS, JAMES F. KEMPE, W. TURNER WOOTON, LOUIS BRECHEMIN, JR., WM. C. MABRY, ROBERT E. NOBLE, LUKE B. PECK, J. RALPH SHOOK, GEORGE WILKLOW, JOSEPH A. O'NEILL, LORIN B. OHLINGER, HARRY J. WATSON, and HOWARD H. BAILY, Army general hospital, Presidio.

MACDONALD, CHARLES E., acting assistant surgeon, Fort Yates, N. D., is granted leave for one month from September 15, provided he furnishes an acceptable substitute during his absence.

JOHNSON, DAVID J., acting assistant surgeon, is relieved from duty at Plattsburg Barracks, to take effect upon the arrival at that post of First Lieutenant William E. Richards, and will proceed to Fort Ontario for duty to relieve Acting Assistant Surgeon George M. Bradfield.

BRADFIELD, GEORGE M., acting assistant surgeon, will proceed to Philadelphia, Pa., and report by letter to the Surgeon-General of the Army for annulment of his contract.

SHELBY, WILLIAM D., acting assistant surgeon, will upon the expiration of his present leave, proceed from Fort Thomas to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

DEWITT, Lieutenant-Colonel CALVIN, deputy surgeon-general, upon expiration of the leave granted him April 21, will proceed to St. Paul, Minn., and report to the commanding general, department of Dakota, for assignment to duty as chief surgeon of that department, to relieve Colonel Joseph P. Wright.

BRECHEMIN, Major LOUIS, surgeon, extension of leave on surgeon's certificate granted to him, is further extended 2 months on surgeon's certificate.

PURVIANCE, Captain WILLIAM E., assistant surgeon, is relieved from further duty at Fort Egbert, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty.

SHAW, Captain HENRY A., assistant surgeon, orders of August 21 are amended so as to direct him upon his relief from duty at the U. S. General Hospital, Presidio, to report to the commanding general, department of California, for transportation to Manila, P. I., where he will report to the commanding general, division of the Philippines, for assignment to duty.

SCHLAGETER, HERMAN J., acting assistant surgeon, is relieved from duty in the department of Alaska, and will proceed to Vancouver Barracks for temporary duty.

MARCH, ROBERT J., acting assistant surgeon, is relieved from duty in the department of Alaska, and will proceed to Portland, Oreg., and report by letter to the Surgeon-General of the Army for annulment of contract.

LITTLE, WILLIAM L., acting assistant surgeon, will proceed from Fort Clark to San Antonio, Tex., and report for assignment to duty with troops of the Twenty-fifth Infantry under orders for the division of the Philippines.

ASHBURN, JAMES K., acting assistant surgeon, will proceed from Batavia, Ohio, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for the division of the Philippines.

WILLIAMS, ABRAHAM D., acting assistant surgeon, will proceed from Jacksonville, Fla., to San Juan, P. R., and report to the commanding general, department of Puerto Rico, for assignment to duty.

CURRY, JOSEPH J., acting assistant surgeon, is granted leave for 1 month on account of sickness.

WINN, Major WM. B., surgeon, the order of July 30 which directs him upon being relieved from further duty in the department of Western Cuba, to proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service, is so amended as to direct him to report to the commanding general, department of California, for transportation to Manila, P. I., to report to the commanding general, division of the Philippines, for assignment to duty.

FIELD, P. C., acting assistant surgeon, leave granted to him is extended 15 days.

SEAGER, HOWARD W., acting assistant surgeon, will proceed from Des Moines, Iowa, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

POPE, Lieutenant-Colonel BENJAMIN F., deputy surgeon-general, now on temporary duty at the Presidio, is assigned to permanent station at that post.

HIGGINS, AUBREY F., acting assistant surgeon, is relieved from duty in the department of California, and will proceed to Philadelphia, Pa., and report by letter to the Surgeon-General of the Army for annulment of his contract.

CURRY, JOSEPH J., acting assistant surgeon, now at Zanesville, Ohio, will upon the expiration of his present sick leave, proceed to Hot Springs, Ark., and report to the commanding officer of the Army and Navy General Hospital for duty to relieve Acting Assistant Surgeon William F. Bernart.

BERNART, WILLIAM F., acting assistant surgeon, will report by letter to the Surgeon-General of the Army for annulment of his contract.

COWPER, HAROLD W., acting assistant surgeon, is relieved from duty in the department of Puerto Rico, and will proceed to Fort Ontario for duty to relieve Acting Assistant Surgeon George M. Bradfield.

BRADFIELD, GEORGE M., acting assistant surgeon, will proceed to Philadelphia, Pa., and report by letter to the Surgeon-General of the Army for annulment of his contract.

The following-named medical officers are detailed to represent the medical department of the Army at the meeting of the American Public Health Association, to be held at Indianapolis, Ind., October 1-5: Major CHARLES RICHARD, surgeon, and Major WILLIAM O. OWEN, surgeon. The officers named will proceed to Indianapolis, Ind., in time to reach there on or before October 1, and upon the adjournment of the Association will return to their proper stations.

Changes in the Medical Corps of the U. S. Navy, for the week ended September 1, 1900:

RIXEY, P. M., medical inspector, commissioned medical inspector from August 24.

SMITH, G. T., surgeon, commissioned surgeon from August 24.

McCORMICK, A. M. D., passed assistant surgeon, detached from the "Chicago," and ordered to the "Montgomery."

WHITING, J. R., assistant surgeon, detached from the "Montgomery," and ordered to the "Chicago."

PIGOTT, M. R., passed assistant surgeon, ordered to the Naval Academy immediately.

CRAWFORD, C. A., assistant surgeon, detached from the "Chesapeake," and ordered to the "Eagle."

SPRATLING, L. W., passed assistant surgeon, detached from the Naval Hospital, Yokohama, upon reporting of relief, and ordered to report to the commander-in-chief of the Asiatic Station for such duty as may be assigned.

BENTON, F. L., assistant surgeon, detached from the Naval Hospital, Cavite, P. I., and ordered to the Naval Hospital, Yokohama, Japan, for duty.

Changes in the U. S. Marine-Hospital Service for the week ended August 30, 1900:

McDOWELL, DR. ALEXANDER, of New York, has been appointed an acting assistant surgeon in the service for duty at Havana, Cuba. This appointment is made at the request of Passed Assistant Surgeon ARTHUR E. GLENNAN. Dr. McDowell has been connected with the service previously as an acting assistant surgeon.

CARRINGTON, P. M., surgeon, granted leave of absence for one month from September 4.

WILLIAMS, L. L., surgeon, to assume charge of purveying depot for 2 days.

VAUGHAN, G. T., surgeon, granted leave of absence for 15 days from September 1.

STIMPSON, W. G., passed assistant surgeon, granted leave of absence for 15 days from August 27.

EAGER, J. M., passed assistant surgeon, granted leave of absence for 4 months from November 30 (permission to go beyond sea).

THOMAS, J. M., passed assistant surgeon, to proceed to Glasgow, Scotland, for temporary duty.

CORPUS, G. M., assistant surgeon, granted leave of absence for 7 days.

THORNBURG, F. J., assistant surgeon, granted 3 days' extension of leave of absence.

FOSTER, J. P. C., acting assistant surgeon, granted leave of absence for 16 days from August 28.

STEVENSON, J. W., acting assistant surgeon, granted leave of absence for 21 days from September 3.

MORRIS, GEORGE A., hospital steward, to proceed to New York (Stapleton), and report to medical officer for duty and assignment to quarters.

WATERS, MARK H., of Vermont, appointed junior hospital steward August 29.

Stump Pregnancy.—John C. Morfitt (*Journal Alumni Association, College of Physicians and Surgeons*, Baltimore, July, 1900) details a case of extrauterine pregnancy occurring in the portion of the tube, the stump remaining from an old operation for removal of ovary and tube on the right; operation was performed while the patient was in the state of collapse with all symptoms of a ruptured tubal pregnancy. Morfitt having removed the right ovary and tube concluded that the symptoms must be due to left-sided pregnancy and, as a preliminary step in the emergency operation removed the left ovary and tube. He then discovered in the stump of the tube formerly removed the existence of a placenta, identifying this as the seat of the pregnancy. From the appearance at the time of operation Morfitt concludes that the fertilizing ovum came from the left side, passed through the left tube and the uterine cavity up into the remains of the tube on the right side where it finally ruptured into the abdomen. He presents the case as evidence that ectopic pregnancy is not necessarily due to mechanical or inflammatory hindrance to the normal downward passage of the fertilizing ovum. [M.B.T.]

Foreign News and Notes.

GREAT BRITAIN.

The University of St. Andrews has received a gift of £20,000 from the Marquis of Bute to establish a chair of anatomy.

The Union Hospital, Belfast.—The late report of the Union Hospital, Belfast, shows that the admissions there during the last 3 years have been larger than in any other hospital in the United Kingdom during the same period.

Drug Adulteration.—A Birmingham chemist has been fined £10 and costs for selling milk of sulphur adulterated with 49% of sulfate of lime, £5 and costs for selling camphorated oil which contained 25% of mineral oil instead of olive oil and 10% instead of 20% of camphor.

A Handsome Hospital Gift.—Mr. John Corbett, of Droitwich, has given a further sum of £10,000 to the Corbett Hospital at Stourbridge, thus making his benefactions to that institution over £25,000. This is irrespective of the value of the house he is erecting in the hospital grounds—a handsome building intended for the dwelling of a medical officer.

Ireland Threatened with Famine.—Ireland is threatened with another famine this winter, due to the failure of the corn and potato crops. Tourists say that the outlook for the natives of the Green Isle this winter is becoming as serious as that of the famine years of 1846–47, when nearly 2,000,000 of people died as the result of the blight of the potato crop.

London Mission Hospital, Chung-King.—A medical branch of the London Missionary Society was started in Chung-King in West China on the Yangtse river in 1892, Chinese buildings being utilized for the purpose. A new building of 3 stories to accommodate 80 patients was opened on December 23, 1899, by Mr. F. A. Fraser, the British consul, including the consuls of France and the United States, Chinese officials, both civil and military, and many others.

David Lewis Northern Hospital.—The completed portion of the David Lewis Northern Hospital at Liverpool was opened on July 30 for the reception of patients without any formality. All the patients have been removed from the old building into the new quarters, which are in every way well adapted to their purpose. There are 150 beds in the portion of the hospital just opened and it affords far greater facilities for the treatment of the sick than were experienced under the former régime.

London School of Medicine for Women.—The rebuilding of the Medical School for Women, in London, is now almost completed. The number of students is about 200, and a very large proportion among them take up the course for the degree of the University of London. The school is unusually rich in scholarships, some of them being of considerable value, though the best of them appear to be reserved for students who are willing to combine missionary work with medical practice.

Plague in Glasgow.—There are 13 cases of plague at present; 3 doubtful cases, and 103 under observation. The disease has spread to Govan, a suburb of Glasgow, where a recent death is reported. A report is current that 2 cases of plague have been discovered near London docks, but the medical officer, when questioned, said he knew nothing about the matter. The Austro-Hungarian Government has ordered a medical examination of all ships arriving from English ports. The presence of plague at Glasgow is commented upon indignantly in Berlin as going to show criminal negligence on the part of British authorities.

Inebriate Homes.—The report of the first year's experience at the Bentry Homes near Bristol has just been issued. The board of management are hopeful of success. They call attention to the difficulties met with owing to the violent character of some of the persons committed to the homes and appeal for them not to be sent. The subject was brought before the Birmingham Justices, August 13, when it

was stated that in the absence of any state reformatory it was not possible to send these cases elsewhere. An opinion was expressed that the violent drunkard might be sent to prison, but it was shown that a short term of imprisonment had no curative effect upon the habitual drunkard.

Consanguineous Marriages and Tuberculosis.—Dr. C. A. Davies, of the Isle of Man, read an important paper on the above subject at the recent meeting of the British Medical Association. Consanguinity in marriage among the Manx people had led, he said, to much illness in the offspring. There has been but little crossing of races among them since the twelfth century, and a custom exists on the island today of discouraging marriages between persons living even in different parishes. Hence there exists all over the island a condition of close "inbreeding." As a consequence the general death-rate from consumption is 25.70 per 10,000, double that of England and Wales. In Lonan the rate is 41.77 per 10,000, while in Peel, where many more strangers come, it is only 15.19.

Marston Green Homes.—These homes were established about 21 years ago by the guardians of the parish of Birmingham in the hope of raising to good citizenship those who had sunk by no fault of their own. They had the merit of being the first homes of the kind established in the kingdom. About an average of 300 children are in residence, with from 20 to 30 boys or girls in each cottage. For the boys a foster father and mother are provided, and for the girls a foster mother. The training is conducted by experienced masters and mistresses and the work is carried out with much zeal and interest. The good result of the management is shown by the fact that there has been only one death, and that there are at present only 6 patients among some 400 children who have gone through the homes during the past year.—[*Lancet*.]

CONTINENTAL EUROPE.

The New German Pharmacopœia.—The fourth, revised, edition of the German Pharmacopœia has just been published. It contains 628 articles, of which 26 are new, while 10 articles, official in the third edition, have been dropped in this.

The Moscow Society of Physiologists has undertaken to issue a journal entitled *Le Physiologiste Russe* which is intended to make the work of members of the society in physiology, physiological chemistry, histology, embryology, general pathology, and pharmacology known to that large section of the scientific world to which Russian is an unknown tongue. Original papers will be published in French or German; and summaries of all Russian work appearing elsewhere will be given in French. The first volume has already been issued.

Typhoid in Paris.—Statistics show that typhoid fever prevails in almost an epidemic form in Paris. There were recorded, from the beginning of the year to August 13, 3,148 cases of this disease, of which 568 resulted fatally. This is a considerable increase over the records of previous years. One of the sources from which Paris is furnished with water is known to be infected with the typhoid bacillus, though the water from all the others is pure. The authorities are compelled to utilize the contaminated source, because the others are inadequate. These statistics may spur the responsible authorities into seeking fresh sources. Parisians are recommended to boil the water they use, or to drink only mineral waters.

Free Clinics and Lectures in Paris.—According to the *Medical Age*, a system whereby all French and foreign physicians may hold clinics, lectures, and scientific demonstrations without cost to themselves has been established at the International Hospital, Paris. The idea which has led to the establishment of this services of conferences is that, owing to the great number of international congresses held in Paris, the attendance of medical men is always large. Many of these have demonstrations to make, for which there is little or no time in the section meetings, and it is for the accommodation of such that the extra service has been organized.

MISCELLANY.

India's Famine.—The Viceroy of India cables that the total number of persons receiving relief is 4,891,000.

Danger of Famine in Tientsin.—Refugees are said to be going to Tientsin, China, at the rate of 1,000 a day. As there is not more than a month's food-supply in the city there is every prospect of a famine shortly.

Quarantine Against Glasgow.—Denmark has declared a quarantine against vessels arriving at Danish ports from Glasgow. The port authorities of Southampton, Liverpool, and elsewhere have already started a special inspection of vessels from the Clyde.

Obituary.—THOMAS HOWDEN, at Maitlandfield, Haddington, August 7.—FRANCIS ALEXANDER MACPHERSON, at Liverpool, August 12, aged 50.—PIERCE ADOLPHUS SIMPSON, of Glasgow, August 15, aged 63.—F. MICHL, of Prague, aged 50.—JOHANN KJELDAHL, of Alt-Karlsberg.—DR. FALCONI, of the Cagliari Medical School.

Medical Congress in Poland.—The universal movement in favor of medical congresses has reached Poland, where a very successful meeting was recently held. The opening address was delivered by Professor Kostanecki, of Cracow, who chose as his theme the universality of medical science. The two principal points discussed by him were the means of combating tuberculosis and alcoholism. The scientific work of the Congress was divided among 24 sections.

Some Old People.—According to the *Indian Medical Record*, more people over 100 years old are found in mild climates than in the higher latitudes. According to the last German census, in a population of 55,000,000, only 78 have passed the hundredth year. France, with a population of 40,000,000, has 213 centenarians. In England there are 146; in Ireland, 578; in Scotland, 46; in Sweden, 10; in Norway, 23; in Belgium, 5; in Denmark, 2, and in Switzerland none; Spain, with a population of 18,000,000, has 401 persons over 100 years of age. Of the 2,250,000 inhabitants of Servia, 575 have passed the century mark. It is said that the oldest person living is Bruno Cotrim, born in Africa, and now living in Rio de Janeiro. He is 150 years old. A coachman in Moscow has lived for 140 years.—[*Medical Age*.]

The Australian Natives Association.—In all the Australian colonies an association exists called the Australian Natives Association, membership of which is restricted to native-born Australians. Its main object is to forward the interests of the native-born and "mutually improve the minds of members by discussing subjects connected with the common weal." In New South Wales the association confined itself to this object, but in Victoria and South Australia the association is registered under the Friendly Societies Act as a benefit society, affording medical attendance, medicine, sick pay, etc., to members. In Victoria the association has flourished, having 17,500 members and assets of about £100,000. In Victoria the A.N.A., as it is called, is the most objectionable of all friendly societies from the point of view of the medical officers. It gives the least remuneration to its lodge surgeons and it admits the largest proportion of well-to-do members who join on the plea that they do not want the medical benefits but are joining a political organization. Once members, however, they always take the fullest advantage of their privileges and are the most exacting of lodge patients.

A Tax for the Tuberculous.—Dr. Phicque has proposed the establishment of an additional tax upon alcohol, of which the profits should be applied to the expenses of the fight against tuberculosis. An additional penny to the present tax of 156 francs per hectoliter would bring in 25,000,000 francs per annum. The French duties are at present much lower than the American, 245 francs; the Dutch, 252 francs; and above all the British, 477 francs per hectoliter. The creation of this duty upon alcohol would be perfectly justifiable, for alcoholism is the principal cause of pulmonary phthisis. With the duty sanatoriums could be built and all the expenses of disinfection could be defrayed.—[*Lancet*.]

1.—The danger of one consumptive in a household infecting his fellows by his sputum is great. As a general rule, the unfortunate member or members of a family who are attacked are young and naturally command a great deal of sympathy. They are looked upon as hopelessly stricken, and consequently are nursed and pampered, to their great detriment. Carefully located in the best room of the house, the fresh air religiously excluded, the windows sealed up, the air impure and overheated, the patient is loaded with woollen clothing and his bed with eiderdowns, he is provided with the very best conditions for his destroyers to flourish. Tubercle bacilli enjoy this treatment, and under these circumstances their work is rapid. The only cure known at present for pulmonary tuberculosis is fresh air and sunlight in a proper sanatorium. The erection of large numbers of sanatoriums throughout the country will do more to solve the difficult problem of how to reduce the mortality from pulmonary tuberculosis and to prevent its spread than anything else. Raw expresses the hope that the day is not far distant when every town and district will have a well-equipped sanatorium in its midst for the treatment of consumption. [J.M.S.]

2.—In nearly all cases, the size of the particles in bacterial filter-beds is such as to preclude the possibility of the mere mechanical separation of the germs. Therefore it may be stated in general terms and with comparative safety that the mechanic separation of the microorganisms in sewage by the use of such bacterial beds is virtually impossible. Whatever chemie and bacteriologic changes may have taken place in the sewers, the sewage is still nearly as dangerous from the epidemiologic point of view when it reaches the filter as it was when it left its objectionable source. If one desires to form any concept of the probable fate of the typhoid bacillus and other pathogenic germs during the biologic process at work in bacterial beds it is necessary to see how other microorganisms, more easily recognized and identified, fare in the strug-

gle for existence. Houston chose *Bacillus coli communis* and *Bacillus enteriditis sporogenes* for the purpose of studying the action of these beds on microorganisms in general. Cultures were made from the sewage as it reaches the bacterial beds and from the effluent as it left the beds after the filtering process was completed. The studies showed that the biologic processes at work in the bacterial beds did not effect any constant or striking reduction in the number of either of the organisms. It may, therefore, be considered as proved that some pathogenic microorganisms pass through the filters in undiminished numbers, and until positive evidence to the contrary is forthcoming, it would be wise to regard the effluents from bacterial beds as no more safe in their possible relation to disease than crude sewage. It is further possible that a bacterial filter may act as a storehouse for pathogenic germs. Certain animal experiments have shown that the tetanus bacillus and the tubercle bacillus retain their virulent properties in the filter-bed. In the discussion that followed the reading of the paper, Dr. J. C. Thresh said that so much stress was being laid upon the improvement of sewage from the chemist point of view that there was a possibility of forgetting that the real danger from sewage arises from the nature of the microorganisms present in it. Dr. A. S. Grünbaum said that he thought that by further examinations with Dr. MacConkey's bile-salt medium it might be possible with comparative ease to isolate *Bacillus typhosus* and that in all probability it will be found to pass through the bacterial beds. Dr. H. Cooper Pattin asked what should be done with the effluents as they leave the filter-beds. Should they be passed over land or over sand beds similar to those used for the purification of water? Dr. Houston said that filtration of the effluent through land of the character mentioned would very materially lessen the danger of such effluent getting into rivers. [J.M.S.]

3.—Kenwood opened the discussion on the action which can be taken by local authorities for the prevention of tuberculous disease, apart from the control of milk and meat supplies, at the section of State Medicine of the British Medical Association. In the first place we all recognize that none of the efforts must be relaxed in the direction of removing those conditions of site, dwelling, occupation, and food, that promote the prevalence of the disease, since the work of sanitary authorities in that direction has reduced such prevalence some 40% among males and 54% among females. We must more especially direct our energies toward enforcing the provisions of sanitary law (1) for the prevention of overcrowding, (2) for securing healthy homes for the lower classes, and (3) for an improved general scavenging. The education of the public as to the circumstances favoring the individual susceptibility to the disease and the conveyance of its infection from the sick to the healthy is essential to any action tending to further reduce the incidence of the disease. Arrangements may be made with the registrar of deaths to advise the medical officer of health of all deaths from phthisis as soon as possible after registration, when the house can be visited, an offer made to disinfect, and a handbill of advice left. The employment of consumptives in the cooking or selling of food should be prohibited as far as possible; and in any case where consumptives must work along with healthy people the superintendent of the works should make the rule with reference to expectoration an absolute condition on all workers. The provision of some measure of hospital isolation is an essential part of an effective scheme to deal with the disease; and what is particularly needed is an isolation home or hospital for each district, and where the medical officer of health and the medical attendant are both able to certify the isolation of the patient is the only measure by which others can be protected. Power should be given and means provided to secure such isolation. The measures already indicated do not reach that desirable standard so far as the masses who occupy lodging houses, poor class tenements, work-rooms, etc., are concerned. It is necessary to know where the infected homes are, and this information can be obtained by notification only. We have, moreover, to bear in mind that a large proportion of the community is by nature indifferent and careless and with these knowledge is rarely acted upon. On this account power is required to enforce certain precautions in homes where the occupants cannot or will not adopt the necessary precaution-

ary measures. In Manchester the following method is in use: Handbills of information and advice are freely distributed as opportunity presents itself. Placards dealing with expectoration are affixed as often as possible in work-rooms and public places. All premises in which a death from phthisis has occurred are visited, advice is tendered, and an offer is made to disinfect. Voluntary notification is in force, for which a small fee is paid to the one making the return. On receipt of the notification a visit is paid to the premises by a medical officer specially appointed and exclusively engaged in this work. The expenditure of about £300 per annum would suffice to operate such a system in a town of 100,000. In the discussion that followed, Dr. E. Barnard Fuller said that in Cape Town they were presented with a problem that did not affect any community in England to the same extent. He referred to the fact that every week large numbers of fresh cases of phthisis seeking health in South Africa arrive in the city. It becomes a question as to whether some restriction should not be put upon this wholesale intake into the city of these vast quantities of virulent cultures of tubercle bacilli which constantly reinfect the place. At present no restriction is put upon this influx, but the time will come when some regulations must be insisted upon in order to ascertain where these infected units go, so that their power for harm to the community at large may be at least modified. [J.M.S.]

4.—In studying the death-rate of rural communities since 1861, Beevor concludes that the insignificance of ease to cause infection of pulmonary tuberculosis is evident. [J.M.S.]

5.—Tew opened the discussion on the provision of cottages in rural districts, and its bearing upon the public health, at the section of State Medicine of the British Medical Association. The bad influence that unsanitary and overcrowded cottages have upon the public health can hardly be overestimated. The foremost evil is the lowering of the individual stamina of those living under bad conditions, rendering them liable to be an easy prey to any general disease to which they have any susceptibility, reducing the working capacity, and inducing premature old age. Next to this come those two most formidable diseases of infant life, whooping-cough, and measles. The cases of phthisis and other diseases nursed at home can only be expected to have the worst chances of recovery, cooped up as they are in rooms often giving less than the cubic space insisted upon in a common lodging house. [J.M.S.]

7.—Figures tend to show that there has been some actual increase in the number of deaths due to carcinoma in the past 30 years, but Scott's impression is that the increase has been much more marked in the professional skill of the medical men certifying. Havilland's theory postulates (1) that in the countries having a high mortality from carcinoma we find that the tributaries of the large rivers rise from soft marshes or easily disintegrated rocks, and these fall into sheltered valleys through which the main rivers flow; (2) these rivers invariably flood their adjacent districts during the rainy season and generally have their waters colored by the suspended alluvial matters; (3) that the districts "characterized by the tertiary and more recent clays and other retentive soils" have a very high mortality from carcinoma. After studying the mortality from carcinoma in East Essex, Scott concludes that we must look for the causes of carcinoma in some other direction than in an alluvial and clayey soil subject to floods, for (1) the disease is less common within the county of Essex, with its clay soil and numerous estuaries, than it is in England as a whole; (2) although two of the unions of this county contain an excessive proportion of marshy land and estuary, yet their death-rate is below that of the county; (3) those parts of the two unions that include the greatest extent of muddy foreshore, creek, and saltings have a mortality below that of the two unions taken together; and (4) the disease is not especially prevalent in those places that are situated on the banks of the fresh water rivers. [J.M.S.]

8.—Pattin thinks that with very definite limitations municipalities should provide common lodging houses and workmen's dwellings. It is desirable, wise, and prudent for a municipality to say: "We will not, out of regard alike for the healthiness of our city and for the welfare of common humanity, suffer any person to be lodged in a common lodging house within our boundaries below a

certain minimum standard of healthiness and comfort; and, to insure this, we will provide such minimum ourselves and leave it to private enterprise to attract custom by offering a higher standard of comfort, etc., for the same money, and for those who desire, and who can pay for it, a higher sum of money." [J.M.S.]

9.—Grünbaum believes that as regards **coloring matters in food** the public is chiefly to blame, but it could soon be educated to a sanitary level. If brightly-colored foods could nowhere be obtained, the public would buy the other. As regards **preservatives in milk, cream, etc.**, the blame seems to rest chiefly with the railway companies and with the ice-vendors. Ice is used far too little in England, principally on account of its exorbitantly high price. The cow-keeper would probably use a refrigerator if ice could be obtained at a reasonable price. The railway companies, however, are the chief offenders. They do not supply refrigerator vans; they require milk cans to be sent open, unless they are full, in spite of the obvious risk of contamination; the rates are too high; and their servants are too careless. These latter seem almost to take a malicious pleasure in putting milk cans in the sun. It would appear, therefore, that we may do some injustice by legislating too hardly for the purveyors of our perishable foods, unless at the same time we require rational treatment of the same from their carriers. [J.M.S.]

10.—The increasing use of **water-gas** by many companies is a source of distinct danger to the consumers. The dangers are very considerable for more than one reason. The leaking of the mains, the leakages from the house-fittings, and the occasional omission to turn off the taps, are sources of great danger. McWalter suggested that carbon monoxid together with other gases might leak through the leaden and composite pipes by osmosis. He suggested that the former gas might get through at a greater rate than the other constituents. [J.M.S.]

11.—As a result of his studies during the past year, Eyre has obtained from **5 specimens of milk, organisms that microscopically appeared to be the typical diphtheria-bacilli**. None of them, however, was capable of initiating lesions in the guineapig resembling those produced by the Klebs-Löffler bacillus. The interest of these observations lies in the fact that it would be quite easy to be deceived by the microscopic appearances of any one of these organisms, and it is imperatively necessary to make biologic and inoculation experiments in order to confirm or to disprove a diagnosis founded upon a morphologic resemblance, no matter how striking. The studies seem to show (1) that several groups of bacilli, exhibiting segmentation, metachromatism and clubbed involution forms, are occasionally present in retail milk; (2) that the bacilli of these groups agree in resembling the bacillus diphtheria to some extent, but are capable of being differentiated from it, and also from each other; (3) that these bacilli arrange themselves, according to their color-production, into three well-defined groups, which are characterized by the coloration of the colonies themselves, yellow and white respectively, in groups 1 and 3, without the nutrient medium being affected, and by the infiltration of the medium by a pinkish color in group 2, the colonies themselves being only slightly chromogenic; (4) that the members of these three groups are nonpathogenic; (5) that the identity of the Klebs-Löffler bacillus can only be established by careful consideration of its biologic and pathogenic characters. [J.M.S.]

12.—During the past 5 years in **St. Helen's**, of the children under 6 months old who have died from diarrhea, 81% were bottlefed. This mortality led Harris to arrange for the supply of **sterilized humanized milk for the use of the infants** of the locality. When the milk arrives at the sterilizing house it is tested to ascertain, roughly, its percentage of cream. It is then diluted by $\frac{1}{3}$ its bulk to reduce the proteids to the proportion usually found in human milk. Cream and sugar are then added to the extent of 2 ounces of each to the gallon of mixture, and a small amount of salt is also added. The milk is then placed in stoppered bottles and sterilized. As soon as sterilization is complete the bottles are put in baskets that hold nine each, each basket representing the necessary amount of food for the child for one day, that is 6 feedings for the day and 3 for the night. Each bottle contains the quantity proper for one feeding adjusted for the age of the child. The baskets are given out to the

mothers, who come for the food, instructions are also given, and data taken for future reference. Two nipples are supplied which must be returned at intervals to be inspected in order to guard against dirt. On Wednesday afternoons the mothers are requested to bring their babies to be weighed. As a result of this system, of the 24 deaths that occurred among 232 children since August, 1899, only 4 were from diarrhea. The cost of installation of this system was £235 2s. 5d. The current expenditure has been £264 11s. 1d. [J.M.S.]

13.—Berry believes that sooner or later municipal and local bodies will be required to deal with the question of the **housing of the working classes**. Private enterprise will not touch it and philanthropy will fall short. The carrying out of the scheme presents many obstacles, but these should not be insurmountable. Overcrowding can be dealt with in this way and where there is an insufficiency of dwellings for the population and private enterprise fails to supply the demand, the local authority ought to step in. It has been stated that 900,000 people live in an overcrowded condition in London and this forms nearly one-fifth of the population. The medical officers of health should carry out the provisions of the Act that has already been passed, taking the worst and most insanitary property first. [J.M.S.]

2.—Some of the discrepancies in the opinions of different authors as to the **physiologic and therapeutic action of digitalis** have arisen from the consideration of its action upon frogs and mammals to be exactly alike. The action of digitalis on the heart of the frog is chiefly due to the effect of the drug on the cardiac muscle. In mammals, on the other hand, the effect of the drug is not only due to its influence on the cardiac muscle, but also to its stimulating effect upon the inhibitory center in the medulla oblongata, and to the indirect action of the drug through the rise of bloodpressure that it produces, which is known to be a stimulant to the inhibitory center. Brunton believes that the contraction of the bloodvessels produced in mammals by digitalis is very well marked, and that it depends partly upon the peripheral action on the muscular wall of the vessels and partly upon the stimulation of the vasomotor center in the medulla oblongata. The diuresis that digitalis produces is probably due to increased bloodpressure within the glomeruli of the kidneys. According to Schmiedeberg, the chief components of digitalis are digitoxin, digitalin, digitalein, digitonin, and digitin. Digitin and digitonin have little, if any, physiologic action, while the action of the other substances is nearly alike in kind, but different in degree. Many of the discordant results obtained by observers may be traced to the variety of the preparation used, since even when one preparation has the same name as another preparation the action may be different on account of the lack of standard methods of manufacture. The **therapeutic**

action of digitalis or of its active principles is as follows: (1) It regulates the heart's action; (2) it assists the failing circulation; and (3) it acts as a diuretic. In cases of palpitation and functional irregularities of rhythm without organic disease, small doses of digitalis are sometimes very useful. The good effects of the drug are well marked in cases of palpitation that have come on from physical strain, or from anxiety or worry. In cases of aortic regurgitation, where compensation is complete, digitalis is quite unnecessary. It is of the utmost service, on the other hand, when the mitral valves become incompetent either in consequence of damage to the valves themselves or in consequence of dilation of the cardiac orifices. It may be of service before the period of complete dilation by lessening the ventricular dilation during diastole and thus diminishing the amount of blood that can regurgitate into the ventricle. At the same time, by contracting the arterioles, it lessens the onward flow and thus in a twofold manner retains the blood in the aorta during diastole, and renders pressure more steady. To get the best results the use of the drug should be accompanied by rest in bed and by massage. In cases of fatty heart and very high tension, digitalis is dangerous. When we find that the heartbeats are feeble and that its sounds are weak disproportionately to the size of the organ we will do well to be on our guard against possible injury from digitalis. If the drug causes contraction of the arterioles as well as of the heart and the latter organ has muscle-fibers in its walls that have undergone fatty degeneration, while the former organs have normal muscle-fibers in their walls, the resistance to the cardiac contractions will be increased and a heart that is already hardly able to carry on the circulation may be still farther hampered by the drug. In such cases if we wish to stimulate the heart by the use of digitalis we ought to lessen the resistance in the arterioles by the simultaneous administration of the nitrites. The same precaution should be adopted when the arterial tension is high and the heart is just beginning to fail. [J.M.S.]

4.—Craig reports the cases of 4 children who had rashes resembling those of scarlet fever, but which he considers not to be scarlet fever. The opinion is based on the absence of sore throat, strawberry tongue, and the atypic desquamation, in one of the cases; and the absence of strawberry tongue, the mild fever, and the absence of desquamation in the other 3 cases. Three of the cases were considered to be instances of **German measles**. [J.M.S.]

5.—A boy in the preeruptive stage of **measles** was admitted to a ward in which there were 19 other patients. Seven of these contracted the disease and of these 5 had well-marked **preliminary rashes**. In 2 cases the eruption was composed of fine papules, 2 were scarlatiniform, and 1 was a blotchy eruption mixed with papules. With the exception of the rise in temperature, the rash was the first manifestation of the disease in 4 of the patients. Koplik's spots were looked for and not found. One of the patients had convulsions before the appearance of the preliminary rash. [J.M.S.]

6.—Walsh has found that **treatment by superheated dry air** is beneficial in (1) nervous affections, such as sciatica, lumbago, writer's cramp, chorea, and local atrophy; (2) painful and stiffened joints and gonorrheal rheumatism; (3) anemia, Bright's disease, asthma, chronic bronchitis, dropsy, dysmenorrhea, and some forms of heart disease; (4) eczematous and other skin troubles; and (5) gout, rheumatism, and osteoarthritis. Four case histories are given. [J.M.S.]

7.—Keith believes that there are 3 questions with regard to **carcinoma** which are of general interest: Whether it is increasing, is it hereditary, and is it curable by operation? The first 2 questions he believes cannot be answered at the present time, but the third he answers in the affirmative. However, he considers 3 years too short a space of time to determine whether a cure is permanent. He cites several cases which have come under his observation. He considers Halsted's operation too extensive for weak subjects. The removal of the breast and axillary glands is not accompanied by any serious risk to life. The removal of the superficial fat of the breast he considers more necessary than the removal of the pectoral muscles as the lymphatics pass freely into the superficial fat, and he believes that the improved results from the modern extensive operations are due to this free removal of fat, more than to the removal of muscles. [M.B.T.]

8.—Oxley reports the case of a boy who was suffering from **scarlet fever**. The patient did well; desquamation began

on the sixth day, and on the tenth day he was allowed to sit up. Two days later the cervical glands became enlarged and tender, and 5 days after that fever appeared which was followed by effusion into the right knee joint and later by subcutaneous extravasation of blood which extended from the nipple to the knee on the left side of the body, and was accompanied by smaller extravasations on the left arm at the insertion of the deltoid muscle; on the back, from the nates to the lower thoracic region; and on the right side from 2 inches above the popliteal space to the crest of the ilium. The urine contained a slight amount of albumin but no blood. [J.M.S.]

9.—Potts was called to see a woman suffering from **tetanic convulsions due to the ingestion of strychnin**. He passed a stomach tube and washed the stomach with mustard and warm water and with plain warm water and the convulsions ceased gradually. Potassium bromid was then administered and at 4 o'clock in the afternoon, about 7 hours after the beginning of the trouble, the patient was able to walk about her room. Twitching continued for 24 hours, but with that exception, recovery was uninterrupted. The symptoms were produced by an overdose of *strychnos ignatii*. [J.M.S.]

10.—Smith reports the case of an inmate of an asylum, 46 years of age, who, during an attack of excitement, produced a **subcoracoid dislocation of the shoulder** by muscular action alone. [M.B.T.]

11.—A male infant was admitted to the hospital with symptoms of **intussusception**. An attempt to reduce this was made by administering high enemas without result. **Celiotomy** was performed and the ileum was found invaginated at the cecum, and extending into the descending colon. It was firmly held, but was reduced by pressure on the colon behind with gentle traction. **Uneventful recovery** followed. [M.B.T.]

New York Medical Journal.

September 1, 1900. [Vol. lxxii, No. 9.]

1. Fibroid Tumors of the Uterus Complicating Pregnancy. LEWIS S. McMURTRY.
2. Atrophic Rhinitis. JAMES E. LOGAN.
3. Report of a Case of Nephrectomy for Ascending Tuberculosis, with Some Remarks on Cystoscopy and Catheterization of the Ureters in Women. HIRAM N. VINEBERG.
4. A Case of Acute Glaucoma with Subhyaloid Hemorrhage Supervening upon Unilateral Retinitis Albuminurica. DAVID WEBSTER and EDGAR S. THOMPSON.
5. The Treatment of Tuberculous and Purulent Joints with Large-Glass-Speculum Drainage and Pure Carbolic Acid, with a Report of Seventy Cases. A. M. PHELPS.

1.—**Fibroid tumors of the uterus**, according to McMurry, when associated with pregnancy, have a much more rapid growth corresponding to the rapid growth of the uterus itself under the stimulus of an increased blood-supply. The bulk of the tumor alone, or an induced peritonitis may necessitate operation; also the presence of the tumor may predispose to vicious insertion of the placenta and to malpresentation of the fetus; or degenerative changes may weaken the uterine wall and lead to rupture; or the tumor by interfering with contraction of the uterus may cause post-partum hemorrhage. The dangers arising from fibroid tumors during pregnancy depend largely upon their position. Quite large tumors located at the fundus may be carried upward with ease and offer no obstacle to delivery, after which they recede with the general atrophic changes in the uterine tissues and sometimes so diminish in size as scarcely to be detected a few weeks after parturition. When the tumor grows from the lower and posterior part of the uterus and has fallen into the Douglas pouch, as it increases in size it will occupy the pelvic basin and absolutely block the pelvic outlet; such a condition requires immediate operation. [W.K.]

2.—See PHILADELPHIA MEDICAL JOURNAL, Vol. V, p. 1004.

3.—Vineberg reports a case of **nephrectomy for ascending tuberculosis**. The patient, aged 47, came under his care after she had been suffering 6 years with painful and frequent micturition. A cystoscopic examination showed an area of redness studded with papules in the left side of

the bladder. Under topical treatment, her condition improved for a time, the papules disappeared but only to reappear higher up in the bladder, until they reached the left ureteral orifice, which ceased to emit jets of urine. A **catheterization of the right ureter** showed the right kidney normal and healthy, but indications all pointed to tuberculosis of the left kidney. The patient at length consented to surgical interference, and the left kidney was removed. The cavities of the excised kidney contained pus and caseous products, the pus having tubercle-bacilli in abundance. After the operation, the condition of the patient rapidly increased, and a year later she had gained 40 pounds, and is now enjoying good health. Vineberg thinks that chronic tuberculosis of the kidney is not an uncommon disease in women, but fortunately, as a rule, it is unilateral, which makes the prognosis of surgical interference very favorable. In this connection, he testifies to the great value of examination by cystoscope in detecting cystitis, and considers the Kelly cystoscope far superior to that of Casper; it is better adapted to aid in diagnosis of the real condition of the bladder; and while the usefulness of the Casper instrument ends here, Kelly's affords us one of the greatest aids in bladder therapeutics by permitting direct applications, with the aid of the sight, to the diseased areas. A case is reported in detail, in which an obstinate cystitis of long standing was successfully treated through local applications of silver nitrate to the diseased parts of the bladder, this being made possible by the use of Kelly's cystoscope. [W.K.]

4.—Webster and Thompson reports a case of **glaucoma** accompanied with subhyaloid hemorrhages coming on after an iridectomy had been performed. The urine of the patient was loaded with albumin and contained numerous casts and glaucoma was supposed to have resulted from an albuminuric retinitis though the unioocular variety is very rare. The eye was finally enucleated because of the oft-occurring hemorrhages and the pain felt in it. Some trouble was experienced in controlling the bleeding after the eye had been removed and pressure bandages had to be used for several days. [G.B.W.]

5.—Phelps says that in treating tuberculous and suppurating joints, the use of **pure carbolic acid** is superior to all other methods of handling these cases that he knows of. He also urges an early operation, to be done just as soon as the diagnosis of abscess can be made, and if done many cases which either die or later require more serious operations would be healed within a comparatively short space of time. [G.B.W.]

Medical Record.

1. The Relative Bearing of the Conjoined Tendon and the Internal Oblique Muscle upon the Radical Cure of Inguinal Hernia. JOSEPH A. BLAKE.
2. The Significance of the Bacillus Coli Communis in Drinking Water. J. H. LINSLEY and B. H. STONE.
3. Pathological Physiology or Experimental Pathology, its Scope and Significance in Medicine. ISAAC LEVIN.
4. The Discovery of "Ureine," the Principal Organic Constituent of Urine and the True Cause of Uremia. WILLIAM OVID MOOR.

1.—Blake calls attention to what appears to be a difference of opinion as to what constitutes the conjoined tendon, so frequently referred to in the operation for radical cure of inguinal hernia. He says the conjoined tendon is usually understood to be the insertion of the lower fibers of the internal oblique and transversalis muscles, extending along the iliopectineal line laterally for a variable distance from the rectus insertion. A careful dissection of this region, especially if the internal oblique be well developed, reveals that as a rule the lowermost fibers of the internal oblique do not enter into the formation of the conjoined tendon, but, arising from Poupert's ligament, in front of the cord, pass parallel with the ligament to be inserted in front of the rectus. The author says a careful examination of the literature on the subject has convinced him that the Baltimore surgeons have referred to the thickened transversalis fascia, when it forms the dorsal wall of the inguinal canal, as the conjoined tendon. He further says this fascia is entirely distinct from the **historic conjoined tendon**, being separated from it by

the main aponeurosis of the transversalis. Although forming the main support of this region it has nothing to do with the operation for radical cure, except in so far as to determine an operative method, inasmuch as only structures that lie in front of it are sutured. The **true conjoined tendon** is ordinarily such a weak affair that it is negligible in operative procedures. It is only exceptionally that either it or the transversalis are included in the sutures in the Bassini operation, except that the sutures placed in the neighborhood of the internal ring may include the transversalis. [A.B.C.]

2.—Linsley and Stone urge the great importance of careful **bacteriologic examination of drinking-water**, in order to determine whether it has been polluted with sewage. They consider that the discovery of Bacillus coli communis is sufficient proof of this. In 509 specimens of water that they examined, they found typical colon-bacilli in 56, and atypical colon-bacilli in 8. Altogether, they said, 78 of these examinations were positive bacteriologically, and only 31 chemically, showing the superior delicacy of the bacteriologic test. They then discuss the colon-bacillus, calling attention to its importance as a pathogenic germ, and describe several cases of enteritis that resembled typhoid fever, but failed to give the typical Widal reaction. They found in the milk-supply of these patients a peculiar actively motile microorganism, that produced gas in glucose media, and gave a typical Widal reaction with the blood of the patients. The source of this bacillus was found to be an old well in the barnyard, the water of which was employed in washing the milk-cans. They believe even in cases of typhoid fever there may be an added infection from the colon-bacillus. The failure to find typhoid bacilli in the water is not necessarily very significant. [J.S.]

3.—Levin writes a long article upon **pathologic physiology**. He believes this is an important branch of pathology, but is more closely related to normal physiology than to morbid anatomy. He then gives in brief form an outline of the pathologic physiology of the circulation including the blood in connection with which he discusses the question of immunity, of respiration, of digestion, of metabolism, in connection with which he discusses autointoxication, of excretion, and the mechanism of heat production and control, and finally pathologic physiology of the nervous system, which is discussed in less than a column. In his conclusions he argues that the study of this subject must be largely experimental, that is, the introduction of new conditions which act upon the certain organs in such a way as to produce abnormal functional activity. [J.S.]

4.—Moor appears to have made the discovery that ordinary urine contains an organic liquid substance that is about twice as abundant in volume as urea, and to this he gives the name **ureine**. The method of its isolation is very complicated. It depends essentially upon evaporating the urine at low temperatures, precipitation of the salts, precipitation of the urea by oxalic acid, and finally extraction of the ureine with alcohol, which is subsequently evaporated. This leaves only the substance itself and the coloring matters, and the latter can be removed by nitrate of mercury. It is about the color of olive-oil, has a slightly bitter taste, and seems somewhat fatty. The specific gravity is 1.270. It mixes freely with water and alcohol, no matter what their reaction. Moor believes that it belongs to the alcoholics of the aromatic series. It is easily disintegrated at a temperature of 80° C., has a remarkable power of absorbing oxygen, and in one case of diabetes it was present at the rate of 6% by volume, and in a case of pregnancy about 2.3%. The power of absorbing oxygen varies considerably in different specimens. Fermentation of the urine—that is, the ammoniacal fermentation of the urine—cannot proceed in its absence except in the presence of considerable heat, and Moor estimates that its potential energy is about 130° C. [J.S.]

Medical News.

September 1, 1900. [Vol. lxxvii, No. 9]

1. Improved Technic for the Cure of Ventral Hernia. M. M. JOHNSON.
2. Differential Diagnosis of Chronic Rheumatism. JAMES J. WALSH.

3. The Essential Conditions for Habitation to Develop and Maintain Healthful Family Existence. ROSA ENGELMANN.
4. Gastroptosis with Special Reference to a New Mechanical Support. H. W. LINCOLN.
5. The Advances in Medicine. MARTIN M. KITTELL.
6. Music Equivalents in Epilepsy. L. PIERCE CLARK.

1.—In speaking of ventral hernia Johnson mentions as a frequent cause the division of the motor nerves, supplying the rectus muscle, in extramedian sections. Johnson goes on to say that the various methods tried up to the present time are of little value for the prevention of these hernias which occur in from 5% to 10% of all cases. He proposes the following operation for the cure of this variety of hernia: An elliptical incision is carefully made a little within the border of the opening in the abdominal wall. The rectus and external oblique are then exposed by dissecting back the skin and superficial fascia. The edges of the opening are trimmed and a No. 25 silver-wire suture is inserted at the upper angle of the opening by lifting the abdominal wall and passing the needle through the peritoneum, rectus muscle and skin, about 1 inch from the free border of the opening. A needle on the other end of the wire suture is similarly passed on the opposite side of the wound. These sutures are inserted at intervals of an inch throughout the entire length of the incision and the subcutaneous tissues and skin are united by continuous sutures of kangaroo-tendon. The ends of the wire sutures are then fastened to a piece of ivory on either side of the wound after the manner of the old-time quilted suture. He reports 2 cases operated on in this way. [G.B.W.]

2.—Walsh describes a number of painful conditions to which the term **chronic rheumatism** is ordinarily applied. The infectious arthritides are now generally distinguished from acute articular rheumatism; that is, the condition whose etiology is not definitely known. Among the forms of so-called chronic rheumatism are recurrent, subacute rheumatism; the abarticular types in children, often called growing pains; persistent joint lesions after acute attacks; and finally chronic painful conditions not due to rheumatism at all. The fact that many of these are temporarily relieved by the coal-tar analgesics is no proof that they are rheumatic. Among these are the pains in the leg in flat-foot, occupation neuroses, traumatic neuroses, varicose veins in the legs, and neuralgia paresthetica. [J.S.]

3.—Engelmann insists that the **unsanitary housing of the poor** is a menace to the health and morals of the community and to the future of the race. She quotes statistics to prove that model tenements are profitable, but believes that suburban homes are a more desirable solution of the problem. [J.S.]

4.—Lincoln supports the abdomen in cases of **gastroptosis** by applying long strips of rubber adhesive plaster, cut into two parts by a curved line. The original piece is 36 x 7 inches. The convex piece is applied so that the ends overlap in the back. The reinforcing curved piece is divided and the broad ends overlap in front. This support cannot slip and is usually quite comfortable. [J.S.]

5.—Kittell mentions briefly some of the modern **advances in medicine**. [J.S.]

6.—Clark reports an interesting case of **epilepsy** in which the patient, a man of 40, and feeble minded, would become rigid and sing for about 30 seconds; he would then stop abruptly, and recover consciousness with anemia, but rapidly become stupid and fall profoundly asleep. In a second case, a girl of 20 years, there were both singing and pseudo angio-pectoral attacks. The former were preceded by gastric aura, then loss of consciousness, and the singing of some religious tune. During this there were sometimes passionate attitudes or states of partial catalepsy. The attacks lasted 20 to 40 minutes. [J.S.]

3. The Injurious Effects of Improperly Constructed School Chairs. J. S. STONE.
4. A Case of Parovarian Cyst, with Twist of the Pedicle Occurring During the Fourth Month of Pregnancy; Operation; Recovery; Normal Delivery at Term. F. B. LUND.

1.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, p. 183.

2.—If the mortality of operations for carcinoma of the breast be usually 10% or more as statistics from certain leading hospitals show, there is doubt, Gage believes, as to the advisability of urging patients to submit to operation. However, many operators have reported long series of consecutively successful cases. Personally Gage has operated on 56 consecutive cases without a death. Inasmuch as recurrences have followed as late as 80 years after primary operation it is more exact to speak of prolonged immunity than cure, and this is an object worthy of our highest endeavor. This is best attained by the most complete operations. Of late Gage has copied Halsted's technic, removing the breast, underlying muscle, and axillary contents in one mass, endeavoring not to cut across the infected tract anywhere from the lower margin of the breast to the apex of the axilla. Out of 57 operations which Gage has performed, 10 are too recent to have statistical value; local recurrences resulted in 27; 8 died from internal carcinomatous disease; 2 from other diseases; and 9 are well and free from recurrence past the 3-year limit, a percentage of immunity of 23½%. Though these results are not what they ought and might be they convince Gage that the complete operation offers long immunity from carcinomatous infection in a large proportion of patients with the hope that this may be permanent. [M.B.T.]

3.—Stone discusses the most desirable shape for the school chair, and urges the great importance of this subject in the development of the individual. The chair should be adjustable to different positions and should support the lumbar spine. [J.S.]

4.—Lund reports a case of **parovarian cyst with twisted pedicle** occurring in the fourth month of pregnancy. The symptoms were severe pains in the inguinal region, and vomiting. The diagnosis was obscure, but the pain persisting an operation was performed, showing a cyst behind and above the uterus with a pedicle twisted on itself 3 times. The cyst was tapped and removed and the pedicle tied off in section with silk. The patient made an uneventful recovery and 5 months afterward was delivered of a boy baby in excellent condition. The swollen turgid pedicle simulated a swollen appendix, preventing an accurate diagnosis, but the wisdom of opening the abdomen in the presence of acute abdominal symptoms even without an exact diagnosis was indicated. Lund attempts to explain the twisted pedicle upon the hypothesis that the tumor lay in such a relation to the pedicle that the movements of the abdominal wall, intestines, etc., twisted it in a given direction, becoming gradually turned several times until finally some slight movement of the woman gave the final twist which produced strangulation and made its removal necessary. [W.K.]

8. The Relation of Surgery to Diabetes. C. P. GILDERSLEEVE.

5. —Andrews reports 2 cases of malformation of the uterus, the first a girl of 12 years, whose symptoms led to an examination showing an absence of vagina with much enlarged uterus and tubes. It was decided to make a vagina, but as the necessary incision and further exploration revealed the absence of both external and internal os and the occlusion of both tubes, it was deemed advisable to remove all these organs and the patient promptly recovered. The second was a case having bicornate uterus, double vagina, double vulva, imperforate anus and recto-vaginal fistula. Two unsuccessful attempts were made to form an

artificial anus during infancy, but the fecal discharges continued per vaginam. A functionally perfect anus was afterward formed at the age of 19 and the rectovaginal fistula closed. The woman subsequently married and after tedious labor gave birth to a perfectly-formed dead child. The manual removal of the retained placenta showed $\frac{3}{4}$ of it in the right horn of a double uterus, and a cord attached to the upper part of the placenta had been compressed where it had passed out of the upper segment. The rectovaginal septum was torn completely through, but was afterward successfully repaired. [W.K.]

Deutsche medicinische Wochenschrift.

4. Enucleation of the Bulb with Substituted Methods, with Especial Review of Sympathetic Ophthalmia. H. SCHMIDT-RIMPLER.
5. My Experience with Light-Therapy. H. STREBEL.

1.—Wassermann found in making bacteriologic examinations in cases of influenza in the past year that bacilli were very difficult to find in the sputum, and it was often difficult to say that the cases were actual instances of influenza. This he found to be true in the cases from several hospitals, and he refers to the work of Clemens, as yet unpublished, in which the same fact was observed. It was also found that though the bacilli were present they vanished very rapidly, and often disappeared after 24 hours. Together with this rapid disappearance of the influenza-bacilli there were often outspoken signs of intoxication. Experimentally the rapid disappearance of the infectious agents and a coincident intoxication always corresponds to the production of bactericidal immunity. Practically all the patients from whom the bacilli rapidly disappeared stated that they had had influenza about ten years before. It was concluded, therefore, that these persons had a remnant of their immunity left which was not sufficient to prevent a new infection, but was sufficient to destroy the bacilli rapidly, and hence in many cases to cause a rapid outbreak of toxic symptoms. Wassermann believes that the peculiar appearance of these cases, differing so largely from those of previous years, indicates that the immunity acquired in the pandemic of ten years ago is being lost, and he considers that we are probably beginning to reach a time when we are once more susceptible and that we may be on the verge of a new pandemic of influenza. [D.L.E.]

2.—Ruge heats the cover-glass in the flame in order to free it entirely from fat, etc., touches the upper edge of the cover-glass to the blood-drop on the finger, and strokes it along the drop so that the lower edge shows a streak of blood 1 to 2 mm. in thickness. The cover-glass is then touched by the under edge to the slide, and while held at an angle of 45° is drawn along the slide, the result being that a thin smear of blood is left along the slide without any pressure having been used upon it. It is then fixed in absolute alcohol for about a half hour only. He then stains with **methylene-blue**. Prepare the stain by adding 0.2 grams of soda to 100 cc. of water; heat to boiling; add 0.3 grams of absolutely pure methylene-blue; allow to cool, filter, and after 48 hours the stain is ready. Pour a little blood on the preparation and wash off with water at once. The red blood-corpuscles stain yellowish-green to bluish green, the ring-forms of the parasites bluish-black, and the larger forms of parasites grayish-blue; and, according to the time which the stain has been allowed to act, the nuclei of the white cells take a more or less intense blue stain. The basophile granules in the red cells come out very clearly. If the stain is to be used with fresh preparations, methylene-blue should be added to the strength of 1%; if old preparations are to be stained, the methylene-blue solution should be largely diluted. [D.L.E.]

3.—Hofmann describes the case of a man of 24 who in the early part of an attack had violent headache. When admitted, at the beginning of the third week, he had the usual symptoms of typhoid fever with marked nervous symptoms. This disappeared after a few days with the exception of slight tremor, this vanishing after about two weeks. Three days

later fever came on again, and there were all the signs of a relapse. There was severe vomiting, but this soon disappeared and there was no headache and no stiffness of the neck. A week later there was severe delirium and stupor, marked restlessness and severe tremor. Five days later the fever disappeared, the patient was clear mentally, and seemed much better. Suddenly there were clonic contractions of the right side of the face and the right extremities, and this continued until death occurred in deep coma 6 hours later. The postmortem examination showed nothing macroscopically except some edema of the membranes and increase of the fluid. Microscopically there was some round cell infiltration of the pia and arachnoid, and some round-cell collection in the subarachnoid space, a round-cell infiltration about the vessels of the brain substance with a few typhoid bacilli in the pia and subarachnoid space. Hofmann speaks of the difficulty of diagnosis. The final convulsions suggested a Jacksonian epilepsy and also uremic convulsions. There were otherwise absolutely no signs of uremia, and this could be excluded. He diagnosed a beginning meningitis, and the postmortem showed that this was present. He discusses the question as to whether the symptoms in such cases are caused by the direct action of the typhoid bacilli or by the typhoid toxin, and states his belief that this case is strong proof of the fact that the toxin is active. He considers that there are but quantitative differences between the usual tremors seen and the more advanced nervous symptoms, up to the actual convulsions seen in this case; and since in numerous cases typhoid bacilli have been apparently entirely absent upon bacteriologic examination, this is a strong negative evidence that the toxin must have caused the symptoms. Even if typhoid bacilli are found in some instances it is usually only in severe cases, such as this, and this only means that since the bacilli are present in the cranial cavity the toxins are produced more rapidly in this region, and have a more direct and violent action. [D.L.E.]

1.—Adamkiewicz calls attention to a peculiar series of phenomena which he believes are the result of **constriction of the central artery of the retina**. It commences with a feeling of tension in the eye, and then a slight veiling of the field of vision. If now the subject looks at a luminous object, the latter appears surrounded by rings which show the colors of the spectrum. The commonest cause of this appears to be a cold douche after a sojourn in a steam bath. Occasionally it may be produced by heat, as for example if a patient sits under a gas flame in the winter and the head becomes warm. It is particularly common at night. It appears to have no clinical significance, but is interesting as showing in certain cases that the sympathetic system may act upon a single small bloodvessel, and it constitutes the first definite proof hitherto offered of the effect of psychical excitement upon the caliber of the bloodvessels. [J.S.]

2.—Toulouse and Rechet have recently devised a method for the **treatment of epilepsy** which consists essentially of rendering the tissues of the organism more susceptible to the influence of bromin by depriving them of the physiologic quantity of the chlorin, that is, a hypochlorination. The clinical tests have apparently been carried out under every precaution and seem to show astounding results. The deprivation is accomplished by submitting the patients to a particular diet consisting of milk, eggs, meat, flour, and potatoes, or else simply a milk diet. In addition, from 30 to 60 grains of sodium bromid are given daily. Nacke, who visited the hospital in Paris in which the experiments were carried out, is delighted with the results and urges all others engaged in the treatment of epilepsy to test this method thoroughly. [J.S.]

3.—Seiffer reports the ultimate results in a case of **Thomsen's disease** that had been operated upon in the fall of 1899, at which time both crural nerves had been stretched. He was able to determine in March of 1900 an atrophy of the right quadriceps, marked hyperalgesia of the inner side of the right thigh, hypesthesia of the inner side of the leg and the lower third of the thigh, and diminution of the myotonic reaction in the right quadriceps with loss of electric contractility in the right vastus internus. On the right side the only change was diminution of the patellar reflex. As far as could be determined, the gait was as typically myotonic as previously and the patient was much disabled by the disease. Therefore, he did not experience any permanent relief and although there was disappearance of the myotonic reactions, it does not appear to have had any beneficial result. The atrophy which was produced in the affected muscles may ultimately lead to serious motor disturbances. [J.S.]

4.—Heldendall reports the case of a woman who had had a cancer of the breast removed, followed by recurrence, and who later complained of headache and slight weakness in the right arm. When examined this was confirmed. There was tenderness in the left frontal region, slight weakness of the left facial nerve, and some papillitis in the left eye. At the autopsy metastases were found in the liver, lung, lymphatic glands, and there was a diffuse thickening of grayish-red color in the dura of the left frontal and parietal regions. Typical carcinomatous-cell groups were found in the dura and also some bony tissue. This condition of **cancerous infiltration of the dura** is exceedingly rare. There was no involvement of the brain itself. [J.S.]

5.—Popoff reports the case of a man of 57, a chronic alcoholic, who had fallen in the street and injured the right arm, giving rise to brachial plexus palsy. Careful examination, however, showed also a slight alteration in the electrical reactions of a few of the muscles on the left side, indicating the existence of **multiple neuritis**. Popoff then quotes the experiments of Siemerling and concludes that various poisons, such as lead, alcohol, etc., may produce changes in the peripheral nerves that can only be detected by alteration in the electrical reaction. He has devised a diagram designed to show the course of an attack of multiple neuritis that consists essentially of a horizontal line from which two inclined limbs descend. The more vertical these are the more rapid the onset or the decline. [J.S.]

9.—After describing a group of cases that apparently arise as the result of **distention of the sinus pyriformis**, which had practically the same symptomatology as the typical Zenker's diverticulum, Starck tabulates 93 cases of the latter condition, and then gives a summary of the results of his investigations. In 79 cases in which the sex was given, 60 occurred in men and 19 in women. In the latter group of cases, however, a distinct cause was given in half. The diverticula varied in size, from a pouch not larger than a

pea to one of the dimensions of an orange. Sometimes the opening into the esophagus is constricted; at other times it is as large as the cavity of the sac. The wall varies considerably in thickness and construction, but up to the present, according to Starck, no case has been reported in which there was a complete layer of muscular fibers surrounding it. The mucous membrane is usually somewhat thicker, and in the submucous tissue there are numerous smooth muscle-fibers and an enormous number of elastic fibers. Sometimes there is in this situation a leukocytic infiltration. Some modification in the position of the surrounding organs, particularly the esophagus and trachea, may be caused, and the wall of the diverticulum is frequently firmly attached to its surroundings. [J.S.]

10.—Strasburger after having noted that in some cases feces that contain considerable quantity of starch failed to ferment, attempted to estimate the amount of **amylolytic ferment** that was present, which he believes may be derived from the pancreas or from the intestinal glands. He employed Robert's method, which consists essentially of mixing the diastatic fluid with a solution of starch, that was always 1% in strength. This was then exposed to a temperature of 40° for a sufficient length of time to enable it to reach the point at which the addition of iodine no longer caused discoloration; 10 ccm. of the starch solution was mixed with 80 ccm. of water, and 10 ccm. of the solution of the feces, and placed in a thermostat. The feces were extracted with water and then thymol added to the subsequently diluted mass in order to prevent the action of the bacteria. The measurement was made by knowing the amount of starch-solution that the feces would act upon or rather the length of time required to convert all the starch into a substance that did not react with iodine. It was found that the amount of amylose in the feces is considerably influenced by pathologic conditions, that it is increased in diarrhea, often decreased in febrile diseases, but apparently is never entirely absent. Certain drugs appeared to have a pronounced effect in diminishing the activity of the ferment, particularly salts of mercury and of silver. The citrate of silver was particularly efficient, and in dilution of 1 to 100,000 caused complete cessation of the action. It appears as the result of some experiments that this ferment arises almost exclusively in the lower portion of the small intestine, although it is possible that in pathologic conditions its source may be more extensive. [J.S.]

11.—Freudweiler, who has had occasion to record the physical condition of patients suffering with pulmonary tuberculosis, has devised a method for **graphically recording** the findings which is based somewhat upon the method proposed by Sahli. There are, however, several very interesting modifications. The diagrams extend from the spine to the axilla, and from the axilla to the sternum. There are therefore 4 for each chest, 2 for each side, and it is possible to make far more complete and more satisfactory records than by the old method of an anterior and a posterior diagram. These diagrams consist essentially of the outlines of the ribs and of the body; a blank space being left for the shoulder. Separate diagrams are employed for percussion and for auscultation. Dulness is indicated by lines crossing each other at right angles, the thickness of the lines and not their closeness indicating the degree of the intensity of the process. A series of curved lines indicates tympanitis. The respiratory rhythm is indicated by a series of squares with alterations in the different lines. In the sides of these squares, marks are introduced which indicate the alterations discovered during inspiration and expiration. The method of recording these changes is somewhat complicated and will require considerable practice before it can be applied to clinical work. Various figures are also suggested to indicate the different forms of rales. The diagrams that accompany this article are not clear. The author, however, states that in the figures ordinarily furnished, the ribs are given in a pale yellow tint, they do not interfere with the distinctness of the records. Even then, they would scarcely equal in distinctness the diagrams that have recently been published by Dr. Musser. [J.S.]

12.—Naegli has carried out a great number of investigations upon more than 50 cases of **typhoid fever**. The blood was examined in each case often more than 15 and sometimes more than 25 times. Differential counts were made. The number of **leukocytes** was estimated and the

conditions found compared with the changes in the clinical course of the case. The technic was painstaking. The conclusions are as follows: Systematic counting of the leukocytes is of value both for the diagnosis and prognosis of the disease. The alterations in the numbers (not necessarily the percentages) of the neutrophile, the eosinophile cells, and the lymphocytes are characteristic in the different stages of the disease, and are produced by the action of the typhus toxins upon the bone marrow, which hinders the formation of neutrophile and eosinophile cells. It is probable that the functions of the lymphatic tissues are also disturbed. The changes are for the first stage—a neutrophilic leukocytosis of moderate degree which rapidly decreases until the neutrophiles are diminished. The eosinophiles disappear and the leukocytes are moderately decreased. In the second stage, the neutrophiles and leukocytes are still further decreased, although the latter towards the end begins to increase again. In the third stage, the increase in the lymphocytes continues, the neutrophiles become even fewer and a few eosinophile cells appear. In the fourth stage, that is during defervescence, the neutrophiles reach their minimum, the lymphocytes are greatly increased and the eosinophile cells gradually return to their normal number. As soon as the fever disappears the neutrophiles commence to increase in number and there is often for some time a considerable lymphocytosis. All these blood-changes are much more pronounced in childhood. In cases of suppurative complications there is usually an increase in the number of neutrophiles. When this fails, the prognosis is exceedingly grave. Favorable indications are the early reappearance of the eosinophile cells, the moderate diminution of the neutrophiles and the extreme increase in the lymphocytes. [J.S.]

13.—Kohler has performed a series of **Widal reactions** with the blood of typhoid-fever patients, using in all instances the quantitative method and repeating the test frequently on the same patient. The blood was obtained by thrusting a minute canula into the vein of the arm. It was allowed to coagulate, and then the serum mixed with the typhoid-culture in various proportions, from 1 to 20 and up to 1 to 180. The cases were all tested in the early stages. The earliest reaction, however, occurred on the third day. In 3 cases reaction occurred after the ninety-seventh day. Altogether 62 cases were tested. Kohler does not believe that the serum-reaction persists for a long time in the blood. In one case the reaction was positive in a dilution of 1 to 20 and doubtful in a dilution of 1 to 40, but the clinical symptoms served to exclude typhoid fever. He therefore believes that unless a positive result is obtained with a dilution of 1 to 40, a diagnosis of typhoid fever cannot certainly be made. During convalescence the blood of the majority of cases showed complete loss of the power of agglutinating typhoid bacilli. Kohler is not of opinion that the Widal reaction will ever be of much use in practical general medicine, partly on account of the difficulties of the technic, partly because the dry method which has been generally employed for this purpose is not sufficiently certain. He gives in tabulated form the results of his investigations. [J.S.]

14.—Schittenhelm reports 2 cases of bronchitis in which firm masses were found in the expectoration. The second case, in particular, expectorated large masses of **bronchial casts**. After various periods of residence in the hospital, he finally died and at the autopsy the bronchi showed cylindrical dilation, but there were no tubercles upon the mucous membrane. The bronchial glands were swollen and cheesy. In the first case, microscopic examination of the expectoration showed the presence of fibrin but not of Charcot-Leyden crystals. In the second case the larger quantity of sputum made it possible to perform some chemical reactions which were as follows: The casts were insoluble in water, ether, or alcohol, although in the latter substance they contracted considerably. They were also insoluble in acids, but dissolved readily in alkaline solutions and were almost completely dissolved by digestion. In hydrogen peroxid they caused rapid evolution of bubbles. It is therefore probable that they contain a considerable amount of fibrin, and as a matter of fact staining by Weigert's fibrin solution showed the presence of this substance. Microscopic examination of the lungs showed a rather extensive tuberculosis of the pulmonary tissue, but no tuberculosis of the bronchi. In fact, the mucous membrane of the bronchial tubes was

practically normal. In the pulmonary tissue a considerable quantity of fibrin was also present. Bacteriologically, only streptococci were found. Apparently there is desquamation from the alveoli of the lung, and masses of fat and epithelial cells are sometimes found in the casts. In regard to the nature of these conditions, Schittenhelm expresses himself as agreeing to the view that they occur acutely and by a process analogous to that in cases of asthma, that is to say—as a result of desquamation itself, an exudation due to nervous influence, and a subsequent coagulation. The nature of the irritation is very various. [J.S.]

15.—Hamel stains cover-glasses fixed in absolute alcohol with Löffler's methylene-blue solution until they have a clear blue color. By this means he has been able to study very readily the **basophilic granulations** of the red cells. These occur, of course, most frequently in cases of **lead-poisoning**, of which he reports 25, and it appears from these that the occurrence of these granular cells is one of the earliest diagnostic signs of lead-intoxication in the human being. If, however, patients have been free of the poison for a long time they may disappear. He also discovered them in one case of pernicious anemia; successive examinations showed a gradual disappearance, and recovery ensued. In 8 cases of carcinoma they were found only in those cases in which there was a very profound cachexia. In 12 cases of chlorosis they were not present with the exception of one in which there was extreme coprostasis. In 9 cases of tuberculosis they were practically not present. They were not found in 7 cases of acute febrile disease, but were present in 2 cases of extreme atrophy with anemia in children, and in a case of purulent perityphilitis. They were not found, however, in 26 patients suffering from various diseases, such as cirrhosis of the liver, myoma of the uterus, degenerative conditions of the heart, nephritis, diabetes, etc. In 24 cases of syphilis the results were always negative. Examination of the other constituents of the blood showed that the presence of these basophilic granules bore no relation to any other form of alteration, which indicates that this is a peculiar form of degeneration. [J.S.]

Revue de Médecine.

1. The Pericarditis of Nephritis. P. CHATIN.
2. Malarial Neuritis. E. SACQUÉPÉE and CH. DOPTER.
3. Agglutinating Curves in Typhoid Fever. Applications of Serum-prognosis. P. COURMONT.
4. Concerning Causes of Error in Experiments for the Determination of the Toxicity of the Urine. T. BERNARD.

1.—Chatin reports 4 cases of **pericarditis** that developed in patients suffering from **nephritis**. Clinically the condition may be acute, subacute, or chronic. In 3 cases with effusion bacteriologic examination showed the fluid to be sterile. In these 3 cases the serum was hypertoxic and, in one in which there was a pleural effusion, that fluid was of a normal toxicity. The toxic elements supposed to be responsible for the inflammation of the pericardium have been found neither in the circulating blood nor in the effusions; and the existence of aseptic and amicrotic pericarditis in certain cases of Bright's disease is well established. The pericarditis of nephritis may sometimes develop as a complication of an ordinary infection. It is usually aseptic or sterile. There is no proof in the cases reported that it is of toxic nature. [J.M.S.]

2.—Sacquépée and Dopter conclude their paper on **malarial neuritis**; they consider the symptoms, the characters, and clinical forms, the pathologic anatomy, the etiology, the pathogenesis, the diagnosis, the prognosis, and the treatment of the condition. [J.M.S.]

3.—The studies of Courmont, which were partly reported in the last number of the *Revue de Médecine*, are concluded in the current issue. The author believes that there is a certain relation between the course of the agglutination and the course of the disease. In a general way, the progressive and regular ascension of the agglutinating power is seen in the normal forms and seems to be parallel with the establishment of the different processes of defense of the organism. If, on the contrary, the defense of the organism is inefficient or irregular the agglutinating power, in the majority of cases,

is slight, becomes lowered, or presents an irregular course. There are, undoubtedly, great individual variations in the determination of the height, form, etc., of the agglutinating curve for unknown reasons. These variations are exercised on a scale more extensive than those that limit the thermic curve. The author concludes that the formation of the agglutinating substance appears to be one of the methods of defense of the organism, or at all events it is parallel to the defensive humoral reactions that mark the curve of the disease. There is, in the curve of the agglutinating power, an element of prognosis, that, added to the elements already known, may be of service in predicting the outcome of a given case. Complications are more frequent when the agglutinating curve is of the type common to grave forms of the disease. The agglutinating curves with a maximum height at the time of defervescence or in the first days of apyrexia, with more or less progressive ascension during the fastigium and a fall, often very rapid, at the end of the febrile period or during convalescence is seen in the great majority of cases of typhoid fever that are benign or of medium severity, terminated by a cure and without serious complications. Curves that are continually low, with or without a fall of the agglutinating power below the maximum, are very often found in hyperinfectious forms of the disease, in prolonged cases, or in those that end fatally. Irregular agglutinating curves, with great oscillations, and early fall, are frequently seen in fatal cases and in grave or prolonged forms of the disease. The fall of the agglutinating power before defervescence is seen in fatal, grave, and prolonged cases. Its significance seems to be more unfavorable when the agglutinating power was originally not high and when it does not subsequently rise. Many transitions are possible between these typical curves. In cases of relapse the agglutinating curve often presents two distinct types, as though they were curves from two different patients. When cure is to be the result the curve is often very high; when death will result the maximum of the curve is ordinarily low during the entire disease and often lower during the relapse. In cases of typhoid fever abnormal either on account of their mildness or their torpidity, the agglutinating power is very variable. [J.M.S.]

July 10, 1900. [20me Année, No. 7.]

1. Tuberculosis. Attempt at Open-Air Cure in Normandy. RAOUL BRUNON.
2. Gastrointestinal Disorders of Nervous Origin. DUBOIS.
3. The Lightning-Stroke Symptom ("Coup de Foudre"). CH. FÉRÉ.
4. Tabetic Nasal Crisis. HENRI JULLIAN.

1.—Brunon draws the following conclusions from a study of the open-air cure of tuberculosis in Normandy: 1. Out of 50 tuberculous patients who have been under observation since 1892, all commenced their cure in Normandy and all have been benefited at the beginning of the treatment. The benefit has raised from several months to 4 years. 2. Fourteen patients have been cured or have received benefit that corresponds to a cure, since they have been able to resume work. 3. The others have died after a varying interval of from several months to 4 years for the following reasons: too late application for treatment, lack of intelligence or refusal of discipline on the part of the patient, laryngeal or other complications. 4. Among the 14 patients cured it is necessary to distinguish two classes: the first class has been cured while living in Normandy winter and summer, and includes 8 patients, 4 cured and 4 greatly ameliorated, but invalids on account of the lung condition. The patients of the second group have lived in Normandy in the summer and in the mountains or at the seashore in the winter. This group includes 6 patients, of whom 5 have been cured and 1 has been lost sight of just when cure appeared certain. 5. The "mixed cure" patients living in the country in the summer and in the mountains or at the seashore during the winter, appears to give the better results. 6. Pulmonary tuberculosis may be treated in all its forms by the open-air method in Normandy, both in winter and in summer. The gravest manifestations, such as laryngeal accidents, are curable in the climate of Normandy, if the treatment is applied methodically and at the proper time. [J.M.S.]

2.—It is puerile to see in the functional disorders of the

digestive system that supervene in the course of nervous affections, nothing but a simple complication or a coincidence. The concomitance is so frequent that it is necessary to seek to establish a relation of cause and effect between these gastrointestinal affections and nervous manifestations or psychoses. The cardinal symptoms of "nervonism" are exaggerated fatigue, exaggerated sensibility, exaggerated emotion, and exaggerated suggestibility. These symptoms may be poorly marked in the healthy individual, but they are well marked in the nervous patient and are, indeed present in some degree in almost every human being. The physician forgets the moral causes that serve to produce these symptoms and seeks often to explain mental disorder by the state of the blood, by diathesis, or by intoxications. Dubois believes that the various functional gastrointestinal disorders are but symptoms of the general lowered tone of the nervous system and that the treatment should be directed toward the nervous system and should not be local. [J.M.S.]

3.—Sexual attraction manifests itself sometimes in an intense manner, under a form of impulsive distraction known as lightning stroke ("coup de foudre.") Fé.é gives the history of two patients who presented this symptom. One was a man of 24, in whom it was a manifestation of epilepsy and was accompanied by vertigo and false recollections. The other patient was also a man, of 52. This patient was a neurasthenic following mental emotions and his neurasthenia was accompanied by a confusion of wants. [J.M.S.]

4.—Jullian reports the case of a man of 55 who had been given to alcoholic and venereal excesses, but who had not contracted syphilis. In this patient the symptoms of locomotor ataxia developed and for 4 years he was subject to crises of sneezing that developed unexpectedly without coryza. The crises were frequent and long; each one was announced by a sensation of tingling and pricking deep in the nasal fossae. There was no paresthesia in the cheeks. These special sensations lasted about 3 minutes and then the attack of sneezing commenced and lasted about a quarter of an hour, during which time he would sneeze 20 times or more. After the crisis ended, the patient experienced no abnormal sensation in the nasal fossa. The crisis was never accompanied by hypersecretion of the pituitary mucous membrane. For several years the patient said that he had no taste when he took food. Very often he had a bitter sensation in his mouth, particularly on the tongue, which was noticed principally at night, and was sometimes so intense that it would waken him, at the same time his saliva, like soapy water, would be secreted abundantly. At the end of about an hour the bitter taste and sialorrhea would disappear altogether. Examination of the sensibility revealed an anesthesia and analgesia of both cheeks, which was complete up to the alae of the nose. There was total anosmia, the sensibility of the mucous membrane of the nose was considerably diminished, the patient scarcely feeling tickling, and there was no sneezing following such stimulation. There was no nasoconjunctival reflex. Taste was practically abolished; the tongue looked normal; the pharyngeal reflex was abolished; there was no trouble with deglutition; and sight and hearing were not modified. The author considers the case to be one of tabetic nasal crisis. [J.M.S.]

Revue de Chirurgie.

July 10, 1900. [20me Année, No. 7.]

1. Abdominal Hysterectomy in the Treatment of Cysts and Solid Ovarian Tumors. E. QUENU and L. LONGEUT.
2. Rhabdomyomas. EDOUARD GENEVEY.
3. Pneumonotomy with Costal Resection for Gunshot Injury of the Lung; Recovery. M. CHRISTOVITCH.
4. Interstitial Cells in the Adult Testicle. B. CUNEO and P. LECENE.
5. Carcinoma of the Large Intestine. R. DE BOVIAS.

1.—Nine cases of abdominal hysterectomy are reported. From a study of these cases and the literature of the subject the following conclusions are drawn: Hysterectomy with ovariectomy is not more grave in its results than the simpler operation. The advantages are the possibility of removing adherent ovarian cysts and of satisfactory autoplasmic treatment of the pelvic organs. This gives security

from postoperative accidents, particularly intestinal obstruction. The operation is indicated in case of cysts and ovarian tumors complicated with inflammatory uterine lesions or lesions of the tubes. In case of ovarian cysts complicated by new formations of the uterus or in case of bilateral ovarian cysts in which it is difficult to obtain a satisfactory pedicle to prevent postoperative hemorrhage. It is contra-indicated in unilateral cysts in young women; also in case of bilateral lesions of the adnexa in which the uterus is healthy and it is possible to secure a satisfactory pedicle by simpler procedures. [M.B.T.]

2.—Genevet defines a **rhabdomyoma** as not simply a tumor of striated muscular fiber, but one in which we find striated muscular fibers of new formation mixed with a greater or less quantity of other tissues. Five cases of tumors of this kind are reported, the first occurring in a child of 2 years, in which there was a tumor the size of a nut in the lumbar region. Operation was performed with a fatal result. In a second case, a man of 58 had a tumor in the upper and lateral part of the neck of 2 months' duration. The patient was cured by extirpation of the growth. In a third case, a man of 32 had a tumor of 6 months' duration in the calf of the right leg. Death resulted 3 months after the operation, from cachexia. In a fourth case, a woman of 50 had an extremely large tumor, extending from the right iliac spine to the left border of the sacrum and outward toward the trochanter. The growth was extirpated, but recurrence occurred and death followed in 6 months. In the fifth case, a woman of 22 had a tumor in the region of the internal condyle of the femur. Extirpation was followed by perfect recovery. On microscopic examination the growth has the appearance of tuberculosis or a musculo-fibrous lipoma. [M.B.T.]

3.—A man of 22, while quarreling with a companion was shot with a revolver at the level of the third left intercostal space. When first seen he was pale from loss of blood. The wound of entrance was immediately closed by an antiseptic dressing. No wound of exit could be found and it was concluded that the bullet must be lodged in the lung. An expectant treatment was followed with the application of ice, small doses of morphia, and stimulants. Three days later there were symptoms of a large pleural effusion with considerable depression and some rise of temperature. On the sixth day the condition had become so bad that the patient seemed about to die from suffocation. In this desperate condition operation was considered advisable. On exploratory puncture in the seventh intercostal space purulent fluid tinged with blood escaped. A free incision was followed by excavation of a large amount of blood and pus. Three centimeters of the chest-wall was resected. The bullet was felt with the finger. A V-shaped flap was then raised over the upper part of the lung, the lung was incised and the bullet removed with forceps together with 3 fragments of gangrenous lung. Hemorrhage was arrested by gauze tampon, and 2 drainage-tubes were inserted. The operation lasted 20 minutes and the patient was freely stimulated and gradually recovered, leaving the hospital completely cured at the end of 2 months. [M.B.T.]

4.—Cunco and Lecène report the results of histologic examination of the testicle in 2 cases in which these organs were removed during operations for the radical cure of hernia. The seminiferous tubules were found atrophic and did not present the figures of spermatogenesis; in other parts of the organs there was remarkable augmentation of interstitial cells. These cells are interesting from their morphologic and physiologic significance and from the fact that pathologic degeneration into neoplasms so often occurs. The authors from their studies incline to the belief that these cellular elements arise independent of the process of spermatogenesis and they suspect that careful histologic examinations in tumors of this kind would furnish direct demonstration of the origin of sarcoma from ectopic testicles. From a practical standpoint tendency to malignant degeneration renders castration desirable in all these cases. [M.B.T.]

1.—The experiments made by the authors have consisted in injecting about one part of iodoform emulsified in 11 parts of oil into dogs, guinea-pigs, and rabbits. In 4 dogs 8 cc. of the solution were injected into the peritoneum and 2 cc. into the knee-joint; in an adult rabbit 2 cc. of the solution were injected into the subperitoneal cellular tissue; and in several guinea-pigs iodoform powder was introduced into the subcutaneous tissue after an incision, which was subsequently sutured. As a result of the injection of the iodoform oil into the serous membrane it is found that an inflammation of a certain intensity is first produced which is characterized by the death of the fixed cells that are in contact with the iodoform and by a more or less considerable attraction of leukocytes. On the second or third day the fixed cells begin to multiply and take on an increased activity. The reaction does not differ materially from that following irritant or necrotic agents generally. The multiplication of cells and the increase of their nutritive activity, which persists for about a week after the iodoform injections, makes an excellent agent for substitutive inflammation. The reaction of the subserous cellular tissue and of the subcutaneous cellular tissue is analogous to the inflammation produced by a traumatism or by an aseptic irritant. While iodoform acts on the tissues, on the one hand, and on the microorganisms and their products, on the other hand, the action on the latter is not very rapid and the disappearance of the microorganisms should not be attributed to its bactericidal power alone. The principal factor in the action of iodoform is the formation of new cells with a tendency to sclerosis, that constitutes a ground unfavorable for the growth of microorganisms. It is possible that the formation of polymorphonuclear leukocytes, plasma cells, and giant cells may play an important part. The following formula is recommended: Iodoform and ether, of each, 10 grams; creasote, 2 grams; sterilized oil, 90 grams. [J.M.S.]

2.—Muller reports the case of a man aged 73, a merchant by occupation. The patient was in the habit of drinking liquors, absinth in particular; for 2 years he had been drunk at least 3 times a week. This habitual state of inebriety was often accompanied by abundant vomiting. In November, 1899, the patient began to complain of violent intermittent pain in the epigastrium which was accompanied by the vomiting of mucus, later of bile, and still later of food after eating. In the night of March 3, 1900, the patient vomited without warning between 2 and 3 liters of black blood. Following this the patient lost consciousness. On admission to the hospital he was found to be much emaciated, his complexion was a dirty yellow, his eyes were haggard, his face was covered with cold sweat, his pupils were very much dilated, and his rectal temperature was 36.2° C. (97.1° F.). The heart was feeble and frequent, and the liver was slightly increased in size, but beyond this physical examination revealed nothing. The patient died 15 hours after his admission to the hospital. The clinical diagnosis was gastric ulcer, carcinoma, and terminal hematemesis. At the necropsy the stomach was found to contain a brownish-green fluid, and microscopically presented the classic symptoms of acute gastritis. The most instructive lesions were found in the esophagus, just above the cardiac end of the stomach the superficial veins were found to be dilated, and in their immediate neighborhood numerous whitish patches studded

with linear ulcerations, recalling the lesions of mucous membrane produced by contact with a caustic. In the upper part of the esophagus, just below the pharynx, there were other varicose veins, but the condition was less marked, although the mucous membrane in their neighborhood presented the same yellowish-white color. The liver presented a marked fatty degeneration. The author considers the following to be the evolution of the case: 1. The local caustic action of alcohol on the mucous membrane of the esophagus and the stomach; **alcoholic phlebeectasis**. 2. Subacute and chronic alcoholic intoxication produced an intense fatty degeneration of the hepatic cells. 3. The alterations in the liver resulted in a marked hemorrhagic action. The case also seems to show 1. that cirrhosis is not necessarily the cause of esophageal varices. 2. That phlebeectasis may be of alcoholic origin. 3. That fatty degeneration of the liver of ethylic origin may be added to the local lesions due to the action of alcohol as a factor in the production of hemorrhage sufficient to explain the gravity thereof. [J.M.S.]

3.—Potain defines the **bruit de galop** as a "triple sound of the heart consisting of the addition to the two normal constituents of a third factor foreign to either of the others which is neither a whistle nor a rub, but a striking noise interposed between the normal sounds in one of the periods of silence." The abnormal sound may be heard either in diastole or in systole from which the designations diastolic, *bruit de galop* and systolic *bruit de galop* are obtained. It may be best marked in the neighborhood of the left cavities or of the right cavities of the heart. Diastolic *bruit de galop* may be differentiated from doubling of the diastolic sound by the fact that in the former, between the added sound and the first normal heart-sound, there is an interval of silence. Further, simultaneously with the added sound there is an impulse appreciable on the chest-wall which has its maximum intensity when produced in the left cavities at the left border of the heart, in a line drawn from the apex to the third interspace. It is best made out with the single stethoscope because the binaural stethoscope will not transmit the chest-wall impulse. The *bruit de galop* is always accompanied by increase of the volume of the heart, although often slightly marked. Among the affections that are accompanied by diastolic *bruit de galop* hypertrophy of the heart from interstitial nephritis holds first place; indeed the occurrence of the *bruit de galop* is a very useful indication of this condition. The phenomenon is frequent in the hypertrophy that accompanies aortic insufficiency; it may also be looked for in exophthalmic goiter and in scarlet fever. In the latter case the occurrence of the *bruit de galop* indicates that the disease has a tendency to involve the cardiovascular system. Diastolic *bruit de galop* produced in the right cavities of the heart has its maximum sound in a line drawn from the apex to the second piece of the sternum, and is then usually accompanied by accentuation of the pulmonary second sound. It is usually due to transitory dilation of the heart of dyspeptic origin. It is often seen in patients suffering from chlorosis accompanied by a large heart, in whom it is also due to dyspepsia; and as a complication in pericarditis. The systolic *bruit de galop* is best heard at the base of the heart near the aorta, whence it is transmitted into the carotids, but it does not extend to the pericardium. It is seen in arterial sclerosis with atheroma, in typhoid fever, in influenza of the typhoid type. The systolic form is of arterial origin, while the diastolic form is a phenomenon of ventricular diastole. [J.M.S.]

4.—A goat into which Metchnikoff injected at several intervals defibrinated human blood, furnished a serum that rapidly dissolved the human red blood-corpuscles. This serum was injected into several leprosy patients with their consent and with great care. Following each injection of **hemolytic serum** there was a certain increase of red blood-corpuscles and of hemoglobin that remained for several days and that increased after repeated injections in increasing doses. The injections were well borne by the patients. When, after more than 2 months of study, the stimulant property of the hemolytic serum and its freedom from danger were determined, it was decided to make a decisive experiment. One leprosy patient received $\frac{1}{2}$ cc. of the serum and another received 5 cc. of the same serum. Both injections caused an increase in the number of red corpuscles and of the amount

of hemoglobin, but to a different degree. Whilst in the first patient the hemopoietic superactivity was kept up for several days only; in the second patient it persisted for 3 weeks, at least. Fifteen days after the injection the number of red corpuscles and the amount of hemoglobin had returned to normal in the first patient and he was given a second injection of 3 cc. of the same serum with like result. At the end of 3 weeks the second patient was given a second injection of 8 cc. with like results. The patients experienced no difficulty during the injections, but said that they felt better, particularly with regard to the neuralgic pains. These results should be interpreted as an example of the general law of the stimulant action of cellular toxins on the corresponding elements. [J.M.S.]

5.—According to Lacour, the **initial phenomenon of labor** is an uteroovarian congestion that sends to the uterus a great quantity of blood, rich in carbonic acid, which, in its turn, acts upon the uterine fiber to set up contractions. Now, the uteroovarian congestion is dependent upon the following mechanism: the **corpus luteum of pregnancy** secretes a substance that paralyzes the uteroovarian vasodilator nerves, the sensory nerves, and the muscle-fibers of the uterus. When this substance disappears, the vasodilator nerves, the sensory nerves and the muscle-fibers regain their physiologic properties; the muscle contracts, and finally expels the ovum. These contractions supervene even when the uterus is empty, as in cases of extrauterine pregnancy. Inevitable abortion may be explained by the same mechanism; women subject to this condition being those in whom the corpus luteum undergoes a hasty physiologic evolution. The uteroovarian congestion and the precocious contractions bring about the premature expulsion of the fetus. In such cases ovarian opotherapy may sometimes prove useful. [J.M.S.]

6.—Guyard concludes that **typhoid myocarditis** is the rule, so far as histologic lesion is concerned, in typhoid fever patients who die, even though they have presented no marked signs of cardiac weakness. It attacks, by preference, those that are predisposed by a cardiac condition that antedates the attack of typhoid fever, and debilitated or aged subjects. Weakness of the first sound of the heart combined with a tachycardia that persists above 100 pulsations per minute, suffices to diagnose the condition. The different signs that characterize the condition are of no diagnostic or prognostic value, when they are isolated. Typhoid myocarditis is a parenchymatous myocarditis and needs often to be carefully sought for with the aid of high powers of the microscope. Its lesions, scattered in patches, involve particularly the muscle-fibers, and, secondarily, the connective tissue and the vessels. Its evolution is extremely variable and a definite prognosis cannot be made in a given case nor at a given period. From the viewpoint of termination the cases may be classed as (1) benign forms, often called nervous troubles or passing unnoticed, seem to be cured without leaving a trace; (2) grave forms, that produce myocardial cicatrices and that may serve as the starting point of a chronic myocarditis; and (3) fatal forms. Death, although it sometimes results from syncope, usually takes place by progressive adynamia. It seems particularly to occur in cases in which the heart was attacked by lesions before typhoid fever developed. [J.M.S.]

7.—There is a special form of pericarditis in which one finds a more or less complete symphysis in the anterior portion of the pericardium and an effusion which may be serous, hemorrhagic, or purulent, collected behind the heart. Massip calls this form **encysted pericarditis with retrocardiac effusion**. The usual causes of pericarditis are the etiologic factors in the production of this form of the disease. Adhesions form easier in front where the heart beats against the chest-wall energetically; then the effusion will be produced behind the heart only. Clinically, the symptomatology is very obscure, and often pericarditis is the only diagnosis that can be made. The gravity of the functional symptoms, the signs of compression of the lung, of the esophagus, dulness in the left posterior region of the thorax, muffling or disappearance of the heart-sounds in the same region coincident with the signs of pericarditis, often slightly marked, are the principal manifestations of the condition. Usually the condition is very grave, even in cases that have been treated surgically; in acute cases fatal termination is the rule. [J.M.S.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

Largin.—Stephenson (*The Therapist*, May 15, 1900) believes that largin is in some respects the best of the synthetic silver compounds. As it contains 11.10% of silver combined with protalbin it is richer in the metal than any of the other compounds. It appears as a gray, granular powder, soluble in hot water. Its solutions are precipitated neither by albumen nor by chlorids, so that it is likely to penetrate in active form more or less deeply into the tissues of the conjunctiva. In most cases the author employs a saturated (10%) solution. In a few cases, such as phlyctenule of the cornea or conjunctiva, he dusted the powder itself over the inflamed parts. The results of his experiments in 100 cases of eye-diseases are thus summarized: In gonococcal ophthalmia largin was distinctly inferior both to protargol and to silver nitrate. On the other hand, in acute contagious ophthalmia, due to the Koch-Weeks bacillus, cure soon followed the daily application of a 10% solution. In this affection largin has two advantages over lunar caustic: it causes little, if any, pain; it never gives rise to a conjunctival eschar. In acute trachoma largin acts admirably. In diplobacillary ophthalmia the zinc salts are preferable. In acute blepharo-conjunctivitis, often the result of infection by pneumoorganisms, largin renders good service, applied both as a 5% ointment and a 10% lotion. In some cases of lacrimal trouble excellent results were obtained from injections of largin in addition to the classical treatment. Under such circumstances the drug seemed to exert almost a specific action against the products of suppuration. The only drawback to largin is its liability to stain the conjunctiva if applied for more than a few weeks. It seems even more likely to cause the discoloration than either lunar caustic or protargol.

Inhalations of Formalin.—Green (*New York Lancet*) claims to have obtained excellent results from inhalations of formalin in phthisis and chronic bronchitis. He recommends the following combination:

R.—Formalin	1 dram.
Glycerin	4 drams.
Water	5 ounces.

To be used from 4 to 6 times in 24 hours. The addition of 10 minims of aromatic spirits of ammonia is recommended when the air-passages are unusually sensitive.

Salipyrin.—Bendtner (*Correspondenz Blatt für Schweizer Aerzte*, No. 2, 1900, and *The Therapist*, April 16, 1900) concludes that salipyrin has a favorable influence on uterine hemorrhages, if there are no severe anatomic changes present. It has a soothing effect upon menstrual troubles and others accompanying uterine hemorrhage. Salipyrin acts exceedingly well in premenstrual and menstrual psychical conditions of depression, although the action is but temporary. The drug is indicated in menorrhagia (with or without diseased adnexa), if not due to cancerous processes, or large tumors, or hemorrhages following parturition and abortion; in climacteric hemorrhages; in hemorrhages occurring some considerable time after confinement or abortion; in threatening abortion; in dysmenorrhea; and in uterine disturbances accompanied by neuralgic and periodical symptoms, and also in menstrual troubles in which no severe disease of the uterus is present.

Rules for Paracentesis in Acute Pleurisy.—J. Mitchell Bruce (*Treatment in Practical Medicine*, 1900) says there are two great clinical guides to the performance of paracentesis: First, lapse of time or duration of the effusion; second, urgency. First, no considerable effusion should, under any circumstances, be kept for more than 3 weeks, unless signs of ebb have commenced and are progressive. Fourteen days would probably be a wiser limit; and, indeed, cases have done well which were not permitted to pass the tenth day, although there was no urgency and fever was still present. If fluid be allowed to remain indefinitely in the chest, the lung and the chest-wall both become steadily more impaired in function, and the difficulty of spontaneous

absorption increases with thickening of the pleura. Only harm can result from leaving it longer. Second, urgency of symptoms demands immediate operation, however long or however short the duration of the case. Urgency is recognized by—(a) Universal dullness of the affected side. This evidence is otherwise described as disappearance of Skodaic resonance at the apex. Some authorities do not wait for complete collapse of the lung, but operate when the fluid signs reach the level of the second rib in front. (b) Signs of pleurisy on the opposite side. (c) Development of rales in the opposite lung. (d) Signs of bronchitis, or of pneumonia. (e) Signs and symptoms of serious embarrassment of the heart, whether by simple dislocation or by associated endo-pericarditis, or by previous valvular disease, or adherent pericardium: pallor, faintness, cold extremities, palpitation, great anxiety, and failing pulse. (f) Signs and symptoms of grave involvement of other organs; subdiaphragmatic abscess, acute or chronic Bright's disease, with severe symptoms, etc. (g) Urgent symptoms of intrathoracic pressure, whatever their cause; persistent dyspnea, even in bed, with cough, frothy serous expectoration, lividity and sweats. (h) Signs and symptoms of increase of effusion after previous arrest or decline.

The Treatment of Whooping-Cough without Drugs.—Norton (*Archives of Pediatrics*, April, 1900) states that 150 children under his care in the New York Foundling Hospital were treated by Bergeon's method, which consists in the administration of carbonic acid by the rectum. Of the whole number 143 were decidedly benefited. The vomiting ceased in a day or two, and the paroxysms rapidly decreased in severity and frequency, but the duration of the disease was not lessened. In 7 cases there was no relief from the treatment. In 20 other cases gas supplied by a manufacturer in tanks was used instead of the nascent gas, and in this series the results were absolutely negative. The good results have been attributed by Ephraim to the extra amount of oxygen that reaches the air-vesicles, where it is exchanged for the extra amount of carbonic-acid gas. Norton also reports 3 cases in which a laryngeal tube was used for intercurrent diphtheric stenosis. The use of an intubation tube of hard rubber was first suggested by O'Dwyer in grave cases accompanied by frequent vomiting. In Norton's cases the cough, so far as expiration was concerned, was not modified, but glottic spasm being prevented by the tube air could freely enter during expiration, and thus the paroxysm terminated abruptly without distress or vomiting. The good results confirmed O'Dwyer's view of the efficacy of the hard rubber tube in severe cases.

Orthoform.—According to the *Medical Review*, June, 1900, Manquat (*Archiv Gén. de Méd.*, April, 1900) writes that orthoform may be applied without danger to ulcerations of the mouth, pharynx, and larynx. It is also particularly useful as an analgesic in dysphagia due to cancerous ulceration of the epiglottis or esophagus. Two and a half grains in cachet will ease the pharyngeal pains of gastric ulcer in five minutes. Orthoform is a reliable analgesic application in cracks of nipple and skin, hemorrhoids, intertrigo, stomatitis, and ulcerations of the tonsils. In dentistry it diminishes the pain of extraction, and when combined with arsenic it lessens the pain from the caustic action of the latter in destroying the pulp. Ginestoux recommends the following application for the destruction of cutaneous epitheliomas:

R.—Orthoform.....	1 dram.
Arsenous acid.....	1 dram.
Alcohol.....	5 ounces.
Water.....	5 ounces.

Orthoform is incompatible with silver nitrate.

Hypodermic Injections of Pilocarpin for Gallstones.—Popham (*British Medical Journal*, June 30, 1900) writes that at the suggestion of Dr. Mitchell, of Durban, he has recently employed in several cases of biliary colic pilocarpin hypodermically in ascending doses. The results were undoubtedly encouraging and only once did the drug give rise to any unpleasant symptoms. The writer regards pilocarpin as more efficient than morphin in hepatic colic, and attributes the good results to the increase of secretions whereby the passages are lubricated and the expulsion of the stone facilitated.

Original Articles.

THE ETIOLOGY AND PATHOLOGY OF EMPYEMA.¹

By JOSEPH McFARLAND, M.D.,

of Philadelphia.

1. **THORACIC** empyema, or purulent pleurisy, is an infectious inflammatory condition of the pleura, characterized by a purulent accumulation in its cavity.

Etiology.—The condition is always infectious but not always specific, as a variety of causes may lead to it. Thus may be mentioned, (1) traumatic injuries of the chest-wall; (2) local disease of the chest-wall and lung; (3) lymph metastasis; (4) blood metastasis.

Traumatic Injuries.—In the greater number of cases, it is comparatively easy to explain the occurrence of empyema after traumatic injuries of the chest-wall by the presence of an external or pulmonary wound through which the infectious agent shall enter. Such lesions are evident in punctured and gunshot wounds, compound fracture of the ribs, hypodermic and paracentesis wounds, etc., but in some few cases it is extremely difficult to see in just what manner the trauma acts. This is well illustrated in a case mentioned by J. G. Sutton (*Lectures on Pathology*, p. 235), who speaks of "having performed an autopsy upon the body of a young muscular man, who died rapidly from suppuration of the pleura after a blow on the side. There were no other lesions."

A traumatic nonspecific purulent pleurisy may be experimentally produced by the introduction of irritating chemical substances—oil of turpentine, etc.—into the pleural cavity. In the traumatic empyemas the cause of infection seems to enter the chest from without, and examination of the pus in such cases usually reveals the presence of staphylococci and other familiar microorganisms.

In speaking of chest-punctures as causes of empyema, some mention should be made of the exploration of the chest by the hypodermic needle, and the withdrawal of fluid through an aspirating needle as sources of infection. Griffiths (*British Medical Journal*, 1887, vol. i, p. 831) in 1887 carefully studied 151 cases of aspiration and found that in two cases only did the fluid become purulent. One of these was complicated with tuberculosis, the other with erysipelas.

2. **Local disease** of the tissues contiguous to the pleura is a fruitful source of empyema. Bronchopneumonia, especially the forms occurring in influenza and tuberculosis; croupous pneumonia, tuberculosis, carcinoma, gangrene, cavity formation, and abscess of the lung may lead to empyema under appropriate conditions.

In tuberculosis, which is the most fruitful source of the disease in adults, the tuberculosis itself may excite empyema, the condition having been observed in primary tuberculosis of the pleura as well as in tuberculosis of the lung, or the disease may lead to empyema by the escape of infectious material from small superficial cavities. If these cavities rupture pneumothorax usually results. In tuberculosis it is possible for empyema to depend upon extension of infection along the lymphatic channels from lung to pleura, but this seems to be quite unusual; for, in tuberculous empyema, the tubercle-bacillus is commonly the only microorganism present, and not infrequently careful search fails to discover any organisms in the pus. The tuberculous em-

pyema commonly develops as a serofibrinous pleurisy which subsequently becomes purulent.

Carious ribs and vertebrae sometimes lead to empyema, though probably more frequently the reverse condition is true and the empyema leads to caries and necrosis of the bone.

Perforation of the diaphragm and the evacuation of a hepatic abscess into the pleural cavity has been known to excite empyema. Carcinoma of the esophagus and even of the stomach may by perforation into the pleural cavity cause purulent inflammation.

The rupture of echinococcus cysts and the escape of their contents into the pleura may lead to pus formation.

Sometimes mediastinal abscesses and suppurating or tuberculous bronchial or mediastinal lymphatic nodes break down and evacuate into one or the other pleural cavity with resulting empyema. In rare cases gumma of the lung, liver, pleura, chest-wall or other tissue may by rupture or otherwise act as exciting causes of purulent pleurisy.

As in the traumatic empyemas, no one specific microorganism covers all these cases, and in each particular condition the present microorganisms are easily accounted for by the primary condition.

3. **Lymphatic metastasis** is probably an important means by which bacteria reach the pleura from neighboring but not contiguous tissues. In some cases it may be that primary inflammatory diseases of the pericardium extend to the pleura by the lymphatics. It may be by the lymphatics that the pleura becomes infected in pneumonia. Sometimes the source of infection seems to be much more remote. Sutton mentions the occurrence of pleurisy in middle-ear disease by an extension of the inflammation to the cellular tissue of the pleura along the sheath of the jugular vein. Wounds of the neck and ligations of the great vessels of the neck have been followed by pleurisy of similar occurrence.

In rare cases peritonitis may extend to the pleura by lymphatic extension through the diaphragm.

4. **Blood metastasis** is typically illustrated by pyemia. The bacteria circulating in the blood may be deposited directly in the pleura with the production of small abscesses which open into the pleura and infect it, or there may be a previous hematogenic septic pneumonia with miliary abscesses and escape of bacteria into the pleura. In some of the infectious fevers empyema occurs either as a complication or a sequel. This is most common in scarlatina, but also occurs in typhoid, measles, whooping-cough and pneumonia. The microorganisms present may or may not be those specific for the respective diseases.

In diseases characterized by diminished resistance to infection, as nephritis, the microorganisms which enter the blood and fail to meet with prompt destruction, may accidentally lodge in the pleura and excite empyema.

I. **BACTERIOLOGY.**—The bacteria most frequently discovered in the pus of empyema are the streptococcus, pneumococcus, tubercle-bacillus, staphylococci, typhoid bacillus, influenza bacillus, Friedländer's bacillus and *Bacillus coli communis*.

The microorganisms found in the pus vary considerably with the time of life at which the empyema occurs. Thus, in children the pneumococcus is most frequently met, while in adults it is the streptococcus. In adults the number of tuberculous empyemas is nearly twice as great as in children. The following table from Netter, who has done the best bacteriologic work upon the subject, will amply explain the differences:

¹ Read April 11, 1900, before the Philadelphia County Medical Society.

	Children.	Adults.
Pneumococcus	53.6	17.3
Pneumococcus and streptococcus ...	3.6	2.5
Saprophytic organisms	10.7	
Staphylococci		1.2
Tuberculous cases	14.3	25.
Streptococci	17.6	53.

1. *Pneumococcus empyemas*.—According to Netter these may be primary or secondary. He thinks the primary forms may depend upon the penetration of the air-cells of the lung so that the pneumococcus may enter the pleural cavity without exciting pneumonia. It is not impossible that the infection is hematogenous.

Netter found the pneumococcus in 53 out of 156 cases studied; Levy found it in 9 out of 17 cases studied, and Prudden found it in 9 out of 24 cases. Netter found that out of 127 cases of empyema of adults 32 (about 25%) were caused by pneumococci, while of 29 cases in children 21 (or nearly 75%) were caused by it. It is, therefore, vastly more common as a cause of empyema in children than in adults.

Koplik found the pneumococcus in 60% of the cases he studied. Hold found pneumococci only in 14 out of 19 cases studied. In the remaining cases the streptococcus only in 3, pneumococci and streptococci in 1, and staphylococci only in 1.

Netter believes that the greater number of pneumococcus empyemas are of secondary origin, though out of 53 cases he could only secure a history of pneumonia in 19.

The pus which characterizes the pneumococcus empyema is usually of the variety known to the older writers as laudable pus. It is thick, rich in corpuscles, and is apt to be viscid. Sometimes it has a peculiar greenish color, though none of these peculiarities are constant and there may be nothing about the pus to suggest from what infection it springs.

2. *Streptococcus empyema* is the most frequent form met with in adults, comprising 56, or 44% of the cases in Netter's group of 127. In 24 cases studied by Prudden the streptococcus was present in 7,—29%. Ferdinand studied 12 cases and found the streptococcus in 6,—50%.

Summing up the subject Whitney (*Twentieth Century Practice of Medicine*, vol. vii, p. 39) finds that the streptococcus is present in about 40% of the purulent pleurisies of adults.

The streptococic form of the disease is usually secondary to suppurative foci elsewhere in the body. The most frequent seat of these lesions Netter believes to be the lung. The pulmonary lesions may be unnoticed or may occur as bronchopneumonia, croupous pneumonia, tuberculosis, bronchiectasis, abscess, gangrene, and neoplasm.

Streptococcus empyema also occurs from suppurations in the mediastinum, peritonitis, subphrenic abscess, and in various infectious diseases, especially scarlatina, erysipelas, diphtheria, and measles. It may also succeed suppurative processes of the limbs.

This form of empyema is usually of acute occurrence and leads to rapid pus-formation. The fluid of the exudate begins as a slightly clouded exudate which soon becomes opaque and purulent. Upon standing the fluid readily allows the contained pus-corpuscles to sediment, and separates into two layers, one of clear fluid and one of thick yellowish purulent deposit.

3. *Tuberculous empyema* is by no means as frequent as was at one time supposed. Of Netter's 156 cases only 15,—10%—were of this nature. Prudden found the

tubercle-bacillus in only 1 out of 24 cases. Koplik in 1 out of 12 cases in children; Ehrlich in 7 out of 19 cases. In the tuberculous empyemas, however, judgment cannot always be based upon the presence of the tubercle-bacillus, as in many cases so few of the organisms are present that their detection is attended with much difficulty.

Ziemssen, Levy, and Ferdinand agree with Netter as to the infrequency of pure tuberculous empyema, while Kelsch and Vaillard believe it common. Tuberculous empyema may in rare cases be acute and rapidly fatal, Osler having seen such cases. Usually it is chronic and often develops to an advanced stage before it is noticed. Usually the patients die of tuberculosis, but in some cases a fair degree of health returns after the evacuation is complete. The pus in this form of empyema is like that of cold abscesses and tuberculous lesions generally, i.e., is thin, watery, curdy, and deposits a powdery or flocculent sediment. It may be somewhat hemorrhagic.

4. *Staphylococcus empyema* usually depends upon the *Staphylococcus pyogenes aureus* which enters the chest from without in most cases, though it may be derived from other staphylococcus foci. The organism is not frequent. Netter met with it in 21 out of 156 cases, 6 times in pure, 15 times in mixed culture; Grawitz encountered it twice out of 48 cases; Prudden in 1 out of 24 cases; Koplik in 1 out of 12 cases.

Whitney says that the organism is always of secondary importance and its associate nearly always determines the character of the suppuration.

5. *Typhoid empyema*. Bacillus typhosus has been found in pleuritic pus by Valentini and by Lorigu and Pensuti in one case each and in two cases by Weinbraud and Spring. The bacillus is usually in pure culture, though it has been found together with staphylococci.

6. *Colon-bacillus empyema*.—Observations are on record in which colon-bacilli have been found in the pleural pus by Vidal, Dumontpallier, and Wendrix. I have been unable to secure the details of these cases.

7. *Friedländer's-bacillus empyema*.—The bacillus of Friedländer has been found in empyema in two cases, one of which is reported by Letulle, the other by Netter.

8. *Gonococcus empyema* has been reported by Bordoni-Uffreduzzi and Mazza. The patient was a young girl, 11 years old, who suffered from blennorrhagia and blennorrhagic polyarthritis.

9. *Influenza empyema* probably commonly depends upon the streptococci and pneumococci, but Pfeiffer has succeeded in isolating the influenza-bacillus from the exudate of empyema in two cases which he investigated.

Bareggi has also done the same in a case of purulent pleuritis following bronchopneumonia.

10. *Miscellaneous*.—Occasional interesting observations upon the microorganismal inhabitants of empyemic pus merit brief mention. Osler says that occasionally psorosperms have been found. Spirilla were unexpectedly encountered in one case and corresponded with the form frequently met with in the mouth. They could not be cultivated. A case of leptothrix empyema in a dog is on record.

Diphtheria-bacilli have been found in empyema occurring as a sequel of diphtheria, though usually the streptococcus would be expected in these cases.

11. *Putrid empyema* is caused by the entrance into the pleural cavity of saprophytic bacteria. The condition usually occurs from cancerous processes of the gastro-

intestinal apparatus which work their way into the mediastinum and gradually invade the pleura, or from gangrene of the lung.

The process is characterized by extreme fetor. The odor is sometimes like that of a privy, ammoniacal and disgusting; sometimes nauseating, sometimes like pickled alcoholic specimens, or sulfuretted hydrogen.

The bacteriologic flora is very mixed, many species both aerobic and anaerobic being present. Of the cultivable forms Würz mentions *Vibrio septique*, the colon-bacillus, *Micrococcus tetragenus*, *Staphylococcus pyogenes*, *Streptococcus pyogenes*, and a proteus common in the intestine.

Of the noncultivable forms *Spirochaeta denticola* of the saliva and others are mentioned.

Würz points out that considerable practical prognostic importance attaches to the bacteriologic study of the pus of empyema. Thus empyema in childhood, caused by the pneumococcus, is quite benign and runs a rapid course to recovery, while that caused by the streptococcus runs a slower course and is more serious. Tuberculous pleuritis is a chronic process usually terminating fatally or lasting for years until tuberculosis or an intercurrent affection carries off the patient or he gradually succumbs to prolonged hectic amyloid disease and asthenia.

Empyema is more frequent in children than in adults. Mackey found that 40% of all the pleural effusions of childhood were purulent, while only 5% of those of adults were so. The disease may occur at any age. Pleuritis has been found in the fetus and in the newborn. The greatest number of cases in adults occur between the twentieth and fiftieth years.

The affection is usually unilateral, though both sides may be affected. The left side is more frequently affected than the right.

II. MORBID ANATOMY.—The pleural cavity in empyema contains pus. The quantity may vary from a few cubic centimeters to several liters, and the quality will vary according to the mode of formation, the duration, and prognosis of the affection.

In the cases which begin with a serofibrinous exudate and later develop into empyema the formation of pus is indicated by a clouding of the liquid, depending upon the presence of a few corpuscles. Later the great increase in the corpuscular elements gives the exudate the typically purulent appearance.

In these cases the amount of exudate is usually considerable before it becomes distinctly purulent.

The cases which begin with pus-formation may be observed at any stage of accumulation, and the quantity of pus may be very small.

In ordinary cases there is a distinct tendency for the pus to separate into layers by the sedimentation of the contained corpuscle. This leaves a fairly clear fluid with a thick, crumbly or flocculent sediment below.

Errors in diagnosis may be occasioned by this sedimentation, as unless care be exercised an exploring needle may withdraw clear fluid instead of pus.

The appearance of the pus varies with different conditions, and in the different infections. It has been shown that in the pneumococcus empyema of children the pus is apt to have a greenish color. In the ordinary streptococcus empyema of adults, it presents the appearance of laudable pus. In the tuberculous cases it is somewhat variable, though usually flocculent and curdy and lacking in healthy morphologic constituents.

The pus has a specific gravity varying from 1.023 to

1.015. It is, of course, rich in albumin and contains glycogen, paralbumin, urea, uric acid, and cholesterin (Naunyn). Sometimes leucin, tyrosin, and xanthin are present. In rare cases crystals similar to those of spermin are present and are thought by some to indicate that the empyema originates from ruptured hydatid cysts.

The pus usually has an acid reaction, but, if infected by saprophytic microorganisms, may become alkaline.

The progress of the disease is frequently associated with changes in the exudate. In individuals with good absorbing powers, as in children, it is possible for the entire exudate to be absorbed. In the greater number of cases, and especially in adults, however, the fluid is absorbed, leaving the corpuscular elements to undergo subsequent degenerative changes. Fatty degeneration, the formation of fatty acids, leucin, tyrosin, cholesterin, etc., take place in the corpuscles, and the inspissation of the solid part of the exudate by the absorption of the fluid, changes the contents of the pleural cavity into a cheesy or crumbly mass of grayish-yellow color. In the course of time lime-salts usually precipitate in this mass, which then becomes dense and gritty.

Changes in the pleura.—In pneumococcus empyema of children the pleura may show surprisingly little alteration, its surface being smooth and shining or slightly dulled and congested. Upon microscopic examination the subendothelial tissue of the pleura is found infiltrated with pus-cells.

More commonly in empyema the pleura participates in the disease-process, and upon its congested and thickened surface flakes of fibrin and shreds of degenerating endothelial tissue are observed. As the empyema continues to increase in size and the pus to act upon and macerate the tissues the pleura may become more and more distinctly covered with a pseudomembranous formation of grayish-white color and loose attachment. When stripped off, this sometimes leaves a shining surface, which indicates that the endothelium is intact, but more frequently leaves a dull, eroded surface, which indicates that the endothelium is destroyed. The nature of the pseudomembranous formation is uncertain. It is thought by most pathologists to originate from the inflammatory exudate by coagulation upon the surface. By others it is looked upon as a product of the degenerating endothelium; by still others, who find that the endothelium is sometimes elevated and covers the so-called fibrin formation, as a product of subendothelial connective-tissue degeneration of the pleura.

In many cases of empyema pleuritic adhesions are observed. They probably depend in a majority of cases upon antecedent troubles. Their formation usually begins at the apices of the diseased lungs, probably because of the quiescence of that part of the pulmonary tissue during respiration, and because the accumulating exudate separates the surfaces lower down.

The adhesions may be inconspicuous, but quite frequently descend nearly to the fluid which becomes circumscribed so as to more closely resemble an abscess-cavity than a purulent collection in the pleural cavity. The corroding action of the pus upon the pleura is quite evident and from prolonged contact it loses the endothelial covering, becomes greatly thickened, infiltrated with pus-cells and forms a true "pyogenic membrane."

In this thickened and altered pleura lime-salts are deposited earlier than in the inspissated pus of the cases terminating by absorption, and sometimes true bone-formation—pleural bones—has been observed.

The pulmonary pleura is even more diseased than the costal pleura, so that in the chronic cases the lung becomes covered with a thick rind which is soft and edematous, necrotic and lacerable so long as there is fluid in the chest, but which transforms into an unyielding callous rind when evacuation or absorption bring about regenerative changes.

Contact with the pus not only affects the pleura, but seems to affect the subjacent tissues as well. We find the tone of the muscles is lost so that in empyema the diaphragm is more depressed than in other fluid accumulations in the chest, and the intercostal muscles indicate loss of tone by permitting the spaces to bulge.

The erosions sometimes progress so that the subpleural and deeper tissues are destroyed and the empyema like other abscesses "burrows" its way to the surface to evacuate. This form is described as an *empyema necessitatis*. Such an empyema usually "points" and if not surgically treated, spontaneously evacuates its contents. By the greater number of writers it is said that the "pointing" and evacuation usually take place, as was first pointed out by Cruveilhier, in the space between the sternal end of the lower costal cartilage and the sternal border, the reason given for this being that the external intercostal muscle is absent and resistance diminished. Eichhorst found that his experience with spontaneously evacuating empyemas did not coincide with this observation, for in nearly all of his cases the perforation of the chest-wall took place in the fifth and sixth intercostal spaces between the mammillary and axillary lines. Osler says the perforation of the chest-wall may occur anywhere from the third to the sixth interspace. According to Marshall, it is usually in the fifth. While usually distinctive enough, the burrowing and pointing of an empyema may become most perplexing by making its appearance in unusual places. Eichhorst mentions a case in which the pus burrowed down behind the peritoneum and suggested a paranephritic abscess. Cases are not lacking in which it descended to Poupart's ligament and simulated psoas abscess. It has been known to reach the knee before pointing. Bouveret described a case that pointed in the lumbar region and simulated a lumbar aneurysm.

When the abscess points the appearances are usually sufficiently characteristic, though they may be mistaken for aneurysm, especially in the cases which pulsate. The skin assumes a reddish or purplish tint and becomes edematous and boggy over the projecting eminence that forms. The tumor fluctuates and not infrequently pulsates.

Spontaneous rupture is usually sudden and a liter or more pus may escape with a gush. In some cases, however, the opening is very small and the pus escapes in drops.

The evacuation may take place from a single opening or there may be several, which may communicate beneath the skin. In a few cases evacuation is followed by closure of the fistula and recovery, but the majority of cases exhibit fistulous communications with the chest, remaining for years. Osler mentions a case given in Copeland's Dictionary of Medicine, of a Bavarian physician who had a pleural fistula for 13 years and enjoyed fairly good health.

As long as the fistula remains open it continues to discharge pus, and the drain upon the system thus incurred ultimately may lead to constitutional involvements such as amyloid disease, of which complication the patients may die if not carried off in advance by

the tuberculosis occasioning the cold abscess or by intercurrent affections.

The erosions caused by empyema are always exerted upon the external tissues, and their movement and evacuation are not always toward the outer surface of the body. Sometimes the lung is eroded and a fistulous communication with a bronchial tube set up. This is a dangerous accident, for in the escape of pus from the tube more pus may enter than the patient can expectorate and he becomes overwhelmed, aspirates pus into the healthy part of the lung and drowns in it. When this is not the case, pneumothorax is nearly always sure to follow.

Sometimes the perforation occurs into the esophagus or into the stomach and the pus is vomited or passed with the feces. The pericardium is sometimes perforated. The mediastinum is not infrequently involved, and an empyema of one side may find its way to the opposite side by fistulae through the mediastinum.

The presence of pus in the pleural cavity gives rise to more or less well-marked constitutional symptoms such as loss of appetite, hectic fever, sweats, and there is always pain of greater or less intensity in the affected side. So soon as the pus is evacuated these symptoms subside. If, however, the fistula heals and pus reaccumulates the symptoms again make their appearance.

Changes in the lung.—It is almost impossible for empyema to occur without incommencing the action of the lung and except in the benign pneumococcus empyema of childhood and possibly a few of the rapid streptococcus empyemas of adults, they cannot occur without leaving permanent changes in the lung. The chronic tuberculous empyema is particularly damaging to the pulmonary tissues.

The immediate effect of empyema is to occupy space so that complete expansion of the lung becomes impossible. As the empyema becomes larger the expansion becomes less and less until atelectasis is almost complete and in exaggerated cases the organ becomes inconspicuous in size, flattened in form and may later not only be atelectatic but also compressed by the increasing fluid. The tissue is solid, airless, tough, leathery, and grayish or reddish-brown or even blackish in color. When incised it is noncrepitant and carnified. The bronchial tubes may appear larger than normal and may contain mucopus.

Few cases reach such a stage of compression and destruction as this, partly because few empyemas become large enough, and partly because of the early formation of adhesions between the pulmonary and costal pleurae in the upper part of the chest. In the event of an increase of pus accumulation after the adhesions form a loculated empyema may result.

When the chest cavity is opened in cases of empyema the lung may not appear and the cavity of the empyema may seem to occupy the entire pleural cavity. This appearance depends upon the fact that adhesions have formed between the lung and less diseased parts of the pleura, while over the exposed pulmonary and costal surfaces the macerated, thickened, and infiltrated pleura is completely changed into a "pyogenic membrane."

In still less marked cases when adhesions are not extensive and the process less chronic, the surface of the pleura becomes infiltrated and thickened and in the repair that follows recovery the thin edges of the lung suffer most.

In chronic empyema the macerating and corroding effect of the pus is exerted in large measure upon the

pulmonary pleura which sometimes become so softened and infiltrated that the pus is permitted to enter the alveolar structure of the lung without actual perforation and be expectorated. That this process is one of infiltration and does not depend upon perforation is shown by the fact that in these cases pneumothorax does not occur.

The absorption of the pus and its entrance into the lymphatic structure of the lung is followed by inflammation of the interstitial tissue of the lung so that pleurogenic pneumonia is usually present in such lungs. If this process is active the dissecting effect of suppuration is very marked, if chronic, the fibrosis predominates and the trabeculae of the lungs are thickened.

The recovery of empyema is followed by further disaster to the pulmonary tissue by the fibrosis that takes place. In mild cases of moderate duration the thickened pleura by its contraction rounds off the sharp inferior edges of the lung and offers some impediment to complete expansion. In bad cases the expansion is greatly or completely hindered by the firm callous rind which forms upon the compressed lung and by its almost cartilaginous consistency prevents expansion.

In the very chronic, exaggerated cases, the atelectasis, carnification, fibrosis, and calcification all cooperate to make any improvement in the condition of the lung impossible.

When such cases recover or improve after evacuation, the lung is unable to expand and occupy its normal position, so the ribs fall, the side sinks in and a marked deformity of the thorax follows.

Empyema with atelectasis and compression of one lung is always accompanied by vicarious action of the other lung, whose tissues are more or less inflated in consequence. In breathing exercises directed towards the expansion of the diseased lung, it is the sound lung that is chiefly influenced, and care should be taken not to have the inspiratory efforts so forcible as to occasion emphysematous changes in the sound lung.

Changes in the thorax.—The formation and continuance of empyema are accompanied by enlargement of the affected side. The diameter of that side is greater than that of its fellow and the intercostal spaces bulge. The diaphragm is pushed down and with it the liver on the right side or the spleen on the left. The heart is usually dislocated toward the opposite side and may embarrass the movements of the normal lung.

During the time that the pus is present in the chest the various adhesions, excavations, ulcerations and perforations already described progress, and in addition there may be erosions of the cartilages and bones with caries and necrosis.

After evacuation and recovery the affected side of the chest usually collapses, and the ribs sink in, the shoulder droops, and the spinal column makes a scoliotic twist toward the empyemic side.

The hope of improvement by gymnastics will often be defeated by the further contraction of the new fibroid tissue in the chest, and all hope of causing the lung to expand in exaggerated chronic cases may as well be abandoned.

Effect upon the respiration.—The empyema with the collapse of pulmonary tissue which it involves is an important hindrance to respiration, so that dyspnea and insufficient aeration of the blood are usual symptoms. In addition to the compromised breathing-space on the diseased side the dislocation of the heart toward the other side increases the difficulty, and from the time

the empyema forms it becomes a source of respiratory deficiency. The described subsequent changes make it impossible for this ever to be overcome and the patient will remain a more or less feeble breather. In some cases, especially in children, the dyspnea may be so slight, however, as to escape observation.

Effect upon the circulation.—The dislocation of the heart by pressure of the accumulating pus is noticeable in most cases, and the pressure and proximity effect is often palpable in the transmission of the cardiac impulse to the purulent accumulation and the occurrence of the so-called *pulsating empyema*.

The dislocation of the heart also makes traction upon and may kink the great vessels, especially at the diaphragmatic orifices, so that the circulation in the lower extremities is disturbed and may show itself in venous congestions.

General disturbance of the venous circulation is also occasioned by the obstruction of circulation in the diseased lung and increased labor of the right side of the heart. Right-sided cardiac hypertrophy is not infrequently observed in consequence of this increased labor.

The disturbed pulmonary circulation, as has been pointed out by Orth, is not infrequently associated with compensatory venous collateral circulations which form between the pulmonary vessels and those of the thoracic walls.

PROSTATIC CALCULUS.*

By JOHN C. SPENCER, A.B., M.D.,
of San Francisco, Cal.

Late Professor of Pathology and Histology, Medical Department University California; Chief of Clinic for Genitourinary Diseases, Medical Department University of California.

A CLEAR distinction should be drawn between essential and adventitious, or so-called exotic, calculus of the prostate. By essential, is meant that form which has its origin in the gland substance, and may eventually, in the course of development, break through into the prostatic urethra. By adventitious is meant that form which originates externally to the prostate, as, in the urinary bladder for instance, and being of relatively small size, finds its way into the prostatic urethra, and thence into the prostatic sinus, or by trauma after lithotripsy, directly into the gland substance. Once lodged, it will increase in size by the accretion of urinary salts in solution, and eventually invade the gland parenchyma, involving the latter to a great extent, and protruding into the prostatic urethra to a small extent. While still in the gland, the composition of the essential form differs chemically and morphologically from that of the adventitious form. This paper will treat of the essential variety chiefly.

From the literature at command, it would seem,—although their presence was observed by Morgagni, who likened them to “small grains of snuff” in appearance,—that one of the earliest, if not the earliest investigation as regards the nature of these calculi, was that of R. Virchow.¹

Again Iversen,² nearly 20 years later, took up the study of the nature and origin of these minute bodies. He describes certain epithelial cells, containing yellowish or brownish pigment. The cell-envelope being dissolved or absorbed, the granules are set free in the parenchyma of the gland. These then form a nucleus

* Read at the Thirtieth Annual Meeting of the California State Medical Society, April, 1900.

about which homogeneous concentric layers are deposited, of a substance giving an amyloid reaction.

Stilling¹⁷ also regards the beginnings of these concretions as being due to degenerated protoplasm of gland epithelia. Around these masses, colloid material is deposited and subsequently, after amyloid degeneration has taken place, the iodine reaction is obtainable. It is not obtainable in the case of the more recently formed bodies. He further considers only such colloid bodies as are formed in adult life, as forming the nucleus of a concretion. Such as are found in childhood or early manhood are usually expelled through the acini and duct by muscular contraction. In advanced age any mechanical interference with the emptying of the gland acini, through muscular weakness or degeneration, results in the formation of a hyaline substance first described by him.

Posner,¹⁸ in 1889, investigating along similar lines, regarded this deposit as due to a coagulation of albuminous fluids, or the saturation of albuminous bodies with lecithin.

The conclusions arrived at by Eastman²⁰ in a very thorough study of the origin of prostatic calculi leads him to the opinion that "Since a positive amyloid reaction appears almost constantly, and since no proofs that the degeneration is of other than amyloid character, are at hand, I believe I may conclude with Hildebrand, that the presence of amyloid matter in the concretions may be fairly assumed."

It would seem fair, therefore, to deduce, from the observations of these various investigators, that the origin of prostatic calculi is to be found in the protoplasm of degenerated gland epithelia, about which colloid material is deposited. This eventually undergoes amyloid degeneration. Subsequently, various mineral salts are deposited about this minute amyloid mass, chiefly calcium phosphate (basic), calcium carbonate, animal matter and some yellow or red pigment. The chief constituent is the basic calcium phosphate—84 parts in 100 according to analysis. The presence of uric acid, ammoniomagnesium phosphate, or calcium oxalate, indicates a communication with the bladder or prostatic urethra, as the last named salts have their origin in the urine.

These calculi may vary in size from $\frac{1}{100}$ of an inch up to the size of an orange. The latter size is usually obtained, however, only after communication is established with the urinary passages, in which event salts from the urine are rapidly deposited.

Upon section, the minute concretions sometimes impart a gritty sensation to the knife, and appear as minute brownish or reddish-yellow, more or less translucent, areas. Upon attempts to section a portion of the prostate, the microtome is usually precipitated into momentary mental anguish as he hears the edge of his blade sacrifice its keenness against one or more minute calculi.

When lying discrete in the substance of the gland, the usual form is more or less spheroidal. When several of increased size are lying in close approximation, the sides become faceted, much after the fashion of biliary calculi.

The consistence of the essential calculi is exceedingly hard, and they present a polished appearance. These qualities are usually wanting in the adventitious variety because of the presence of urinary salts.

The diagnosis depends to some extent upon the symptoms, to some extent upon the size. The small

calculi cause no symptoms whatever; even comparatively large calculi may exist without producing any subjective symptoms. Objective symptoms, such as either an intensely hard mass upon rectal palpation of the gland, or this, coupled with obstruction to the outflow of urine from the bladder, should arouse suspicion of the presence of a calculus. I have found an intensely hard mass in the lateral lobe of the prostate in a man aged about 26, seen through the courtesy of Dr. G. W. Davis, in which the sensation imparted to the finger was that of a calculus deeply imbedded in the gland parenchyma. This eventually proved to be composed of some benign tissue, not calcareous, although no microscopic examination was made. In some doubtful cases a sound in the bladder may afford assistance.

When an essential prostatic calculus may have attained such size as to have eroded through into the prostatic urethra, or when a vesical calculus lodges in the prostatic sinus, the tip of a metallic instrument striking against the projecting portion would reveal its presence readily. When the calculi are multiple and lying in a closely investing pouch, or in a cyst or abscess, a crackling sensation may be imparted to the finger examining by rectum. The only other condition which might simulate the presence of prostatic calculus would be the presence of tuberculous nodules in the gland.

The symptoms only become manifest when the calculus may have eroded through into the urinary passages, or, by its size, either paralyzes the vesical sphincter causing incontinence; or produces vesical irritation and tenesmus, simulating the presence of vesical calculus and its concomitant symptoms; or produces, as in my case, an obstruction to the outflow of urine.

Prostatic calculi have been observed in youth and at varying ages up to very old age.

R. Virchow² describes the occurrence of prostatic concretions in the female prostate—the existence of such an organ having been described by Leukart.³ They are uniformly found in the gland acini and crypts, surrounded by epithelia. Externally they are soft, internally more dense, brown in color and formed of concentric layers.

Friedel⁴ reports a case occurring in the prostate of a man dead at the age of 52. On cutting into the gland, the knife came in contact with some substance producing a gritty scratching sound. Secretion collected by scraping the gland parenchyma revealed many crystals, fragments of minute calculi, which were composed of calcium phosphate.

Paulieki⁴ found at autopsy upon the body of a 73-years-old man, 240 calculi above the size of a barley-corn. The largest was 6 mm. in diameter and weighed 2.7 grams. Many were faceted. The majority showed the formation by concentric layers. Only the smaller ones gave the iodine reaction. The composition of the larger ones was not given. The largest had perforated through the floor of the prostatic urethra and protruded about 1 mm.

Edward Morris⁵ reports a case in which from a cyst in the middle lobe of the prostate 5 calculi of a total weight of 20 grams were removed.

G. Gross⁶ reports a case of urethroprostatic calculi operated on by a perineal button-hole incision. In all 67 grams were removed, of which the heaviest weighed 40 grams.

Von Thaden⁸ describes a case in a patient aged 70. The man had had bladder-symptoms for 4 years. The

prostate was enlarged and of stony hardness on rectal palpation. A metallic bougie introduced into the urethra impinged upon a calculus in the prostatic portion which it could not pass. A cut into the gland through the anterior rectal wall revealed a pear-shaped calculus imbedded in the gland, 51 mm. in diameter, weighing 40 grams, which was removed. Result was a cessation of dribbling with a slight remaining recto-urethral fistula. The calculus had a uric-acid nucleus with a calcium carbonate envelope. (This calculus must have had an extraprostatic origin.)

Hattute⁹ operated upon a patient aged 45 years, by a Nelaton preanal incision. Two small calculi were removed. Supplementing this with a lithotripsy through the bladder-floor, through an opening previously present, a calculus the size of an orange, weighing 150 grams, was crushed and removed. It was composed of calcium carbonate and oxalate, uric acid and triple phosphates. The only sequel was incontinence due to pressure-atrophy of the sphincter vesicae.

Stöcker¹⁰ reports a series of interrupted lithotripsies on an individual aged 64 years, from two pouches situated in each half of whose prostate he removed calculous contents. Finally, with a spoon-shaped Civiale lithoclast he removed the balance, 12 grams in all. The composition was calcium phosphate and carbonate, triple phosphate, a small amount of calcium oxalate, uric acid and albuminous material.

Van Imschoot¹¹ reports the case of a patient aged 29 years, who had suffered for 5 years from dysuria and latterly enuresis. He had frequently voided faceted calculi with his urine. A sound introduced evoked grating, but no evidence of a vesical calculus. Rectal palpation revealed a hard, nodular, painful tumor about the size of a child's fist. By a perineal incision 9 calculi, 8 grouped about a central one, were removed. The composition was calcium phosphate, with a small amount of calcium carbonate and oxalate and the result, an unimportant fistula.

Mr. Christ. Heath¹² describes the conditions in a patient aged 58, as follows: He had been passing a catheter for 17 years; had complained of various urinary difficulties referred to urethra and bladder. Six days after admission to hospital, the presence of prostatic calculus was suspected. Through a perineal incision the finger touched a calculus in the prostatic urethra. Three in all were found. They were smooth, of a reddish-brown color and faceted; their total weight about 6.5 grams; composition calcium phosphate and carbonate.

Naumann¹³ reports a case in a boy, aged 13, with symptoms of stone in the bladder. A lateral perineal section into the bladder failed to reveal a stone. Two months later through a median section, a walnut-sized stone, in a diverticulum of the prostatic urethra, was found. Later the patient evacuated small concretions.

Philip Emmerling¹⁴ performed a prostatotomy through a lateral perineal incision on a boy, aged 12. A calculus the size of a hen's egg was removed; composition not given; recovery complete.

Underhill¹⁵ removed a calculus from the prostate of a boy, aged 6, with symptoms of incontinence and dysuria. A metal instrument failed to discover calculus; soft instrument gave a grating sensation. A median perineal incision revealed where the prostate had been. In its place was a calculus which had apparently come from the bladder and lodged in the prostatic sinus. Its weight was nearly 10 grams; its diameter a little over 4 cm.

Delépine¹⁷ gives the history of a case, in which there was 6 years of difficult urination. Examination revealed a prostatic and periprostatic abscess, cystic dilation of the gland and the presence of calculi in the cyst.

Keyes¹⁸ reports a case in which he removed many concretions the size of a hemp-seed from a prostatic abscess, by perineal section.

Moullin¹⁹ under the title of "Suprapubic prostatectomy," describes two cases, in both of which calculi existed in retroprostatic pouches.

Eastman²⁰ in a careful investigation regarding the nature and origin of prostatic calculi, examined 24 prostates postmortem from individuals between the ages of 14 months and 74 years. Concretions were found in all but the youngest and in a boy of 7 years.

Bangs²¹ quotes Ashhurst, who in turn refers to Barker of Bedford, England, who removed a calculus from the prostate of a patient, aged 29, who had suffered from incontinence for 4 years. This calculus consisted of 29 pieces, white in color, very hard and cemented together, measuring about 12 cm. across. According to Bangs, Henry Morris²² removed between 200 and 300 concretions from the same prostate at different sittings; Bangs also refers to a case reported by Erichsen, in a patient, aged 19, with two calculi in his prostate.

In Bangs' own case, 29 calculi were found. Their composition was given as calcium phosphate.

Estes²³ reports a case of multiple prostatic calculi coupled with an encysted vesical calculus.

Mastin²⁴ removed numerous calculi from the prostate of a patient, aged 46.

White and Martin²⁵ describe the removal of 10 prostatic calculi from one patient by means of a slightly curved urethral forceps.

Lydston²⁶ refers to a case of Thompson, in which 9 fragments of prostatic concretions were found, weighing nearly 100 grams.

The above references cover a period dating back to 1851. Undoubtedly prostatic calculi have existed sporadically in human beings, but little or no authentic cognizance of their presence was taken, up to within comparatively recent times.

My own case occurred in a man, aged 59, with an unusually exemplary history of temperate and continent living, having raised a family of 13 children. He was very well preserved, and did not look his age by several years. His symptoms dated back something over 5 years. At first there was some slowness and difficulty in micturition. Examined at one time by W. T. Bull, in New York, a prostatic hypertrophy was diagnosed, and a radical enucleation proposed, but refused. No mention was made at that time of the presence of a calculus in the prostate and its presence was evidently not recognized. Vesical calculus was searched for, but not found. Something over a year ago, he was examined by a physician in his own city. A cystoscopic examination was made, which caused him great distress at the time, and which was followed by traumatic double epididymitis. No calculus was discovered at this time. His case was regarded as one of simple prostatic hypertrophy. From the date of the cystoscopy, he was unable to pass his urine voluntarily, and became an unwilling votary of the catheter. Referred to me by his family physician for radical treatment of the prostatic hypertrophy, I examined him carefully for a vesical

calculus without finding one. The urine showed only moderate turbidity, due to a small amount of mucopus and phosphates. Residual urine about 50 grams, acid in reaction. His bladder-symptoms at no time amounted to more than his inability to urinate spontaneously. He used the catheter between 4 and 6 times in the 24 hours. Rectal palpation failed to reveal more than a uniform prostatic enlargement, one lateral lobe being slightly larger than the other. The searcher sound entered the bladder with comparative ease, indicating no excessive degree of middle-lobe enlargement. A galvanocautic prostatotomy with the Bottini-Freudenberg incisor was advised, as affording a reasonable prospect of relief from his symptoms. The operation was performed under strict antisepsis with eucain-B. anesthesia. The progress of the blade through the central lobe seemed to meet with rather unusual resistance, but no sound was heard or sensation imparted to the instrument which seemed other than due to its passage through tissue. Upon removal of the instrument, an examination showed the cutting blade to be slightly bent and partially covered with what appeared, to the eye and touch, to be calcareous or phosphatic material. It was evident that the blade had passed through, and probably split, a calculus imbedded in the substance of the middle lobe of the prostate. Judging by the mark on each side of the blade of the incisor the calculus must have been at least as large as a large sized hazelnut. The patient's retention was not relieved, although for the first few attempts at urination immediately after the operation, there was very slight dribbling. The first few catheterizations brought away a small amount of calcareous detritus. Catheterization was obligatory and has been continued up to the present. The patient took a radically conservative view of any further attempts to relieve his disabilities, not even permitting an examination of any character. Catheterization was not at any time painful after operation. Reaction was nil. Patient returned to his home in a distant city with the, to him, melancholy satisfaction of having passed through a fairly formidable surgical procedure, and having learned that he had a prostatic calculus which was presumably the cause of his retention. For his subsequent relief, my preference would have been for epicystotomy, and an attempt, by this route, to shell out the two halves of the split calculus. As his hypertrophy was not of an excessive degree, it seemed, that simply removing the calculus, coupled with the contraction incident to the galvanocautic incisions, might afford him the desired relief.

A diagnosis of calculus having been made, depending somewhat upon the size, it would seem as though the method of relief affording the least difficulty would be by the perineal route, and by means of the preanal, semilunar incision. In the case of certain of the very large adventitious calculi the combination of both the superior and inferior routes might be advisable. As seen by the cases of Hattute and Stöcker, a lithotripsy was successful in removing the calculi and their detritus.

One striking fact stands out in the case of my patient: the ease with which a fairly large calculus was completely overlooked. It is only fair to assume that, according to the natural history of prostatic calculi, this one must have been many years in developing. The fact that its presence was not detected by competent observers should serve as a stimulus to more painstaking methods of diagnosis.

In this case the presence of the calculus probably explained the obstruction in urination, in which the lateral gland hypertrophy played only an unimportant role.

HEROIN IN THE TREATMENT OF PHTHISICAL COUGH
AND WHOOPING-COUGH.

By M. LOEWENTHAL, M.D.,
of Brooklyn, N. Y.

At the present time the therapeutic properties of heroin are being so widely discussed in medical journals that I have thought it of interest to place on record here my personal experience with this new drug in a class of cases in which no extended mention has thus far been made in the literature, namely, the treatment of whooping-cough. The few histories of cases of phthisis which are subjoined will also serve to illustrate its action in the latter disease.

Heroin is a white crystalline powder, soluble with difficulty in water, but freely soluble by the addition of acetic acid without chemical change. It is a new morphin-derivative, having the chemical formula:

being a morphin $\text{C}_{17}\text{H}_{19}\text{NO}_3$ in which the two hydroxyl groups are substituted by acetyl radicals, thus producing a diacetic acid ester of morphin.

The results published by Floret, Dreser, Strube, Eulenberger, Leo, Manges, Lang, Weiss, Freudenthal, Fulton, Daly, etc., show heroin to be a cough sedative, analgesic, and antispasmodic. It is less narcotic than morphin, produces no disagreeable effects, such as nausea or vomiting; neither is there any danger of producing a toxic action with medicinal doses. Sometimes it will produce a feeling of lassitude which quickly passes off. In some cases there is a slight tendency to constipation, but by combining the drug with extract of rhubarb or aloin this is remedied. I noticed a dryness of the throat in some instances, which was relieved by a draught of hot water, or by the suspension of the remedy for a day. A few cases showed pruritus, which also passed away when the drug was discontinued for a day or so, and did not reappear upon recommencing its use.

In comparison with codein, heroin has been found to be more powerful and uniform in action. It acts as a sedative to the cough centers, stimulating the respiratory muscles and centers. The checking of the cough by heroin is due to its effect in reducing the number of respirations per minute and increasing the length of inspiration; thus the respirations become more prolonged owing to a larger amount of air being inspired into the lungs with greater force. The dosage of heroin is from $\frac{1}{12}$ to $\frac{1}{8}$ grain. Heroin hydrochlorid being easily soluble in water can be used hypodermically in doses of $\frac{1}{24}$ grain, the dose by the mouth being the same as heroin.

I have used heroin in 13 cases, 3 being cases of tuberculosis, and 10 cases of whooping-cough. In the latter disease few observations have been published, and when I began treatment with heroin, I looked upon it rather sceptically; for previous to the introduction of this remedy we have had hundreds of drugs, all claiming to be specifics for this malady. While I do not say that heroin is a specific, it certainly is most excellent in the treatment of pertussis. The following are the results of cases treated with heroin. In the complications noted below, as asthma, etc., heroin acted admirably.

CASE 1.—Joseph H., aged 28, pulmonary tuberculosis, has been coughing for five months. Before the present trouble began he weighed 137 pounds; but has since declined steadily, lost strength and appetite and felt miserable, his weight being reduced to 99 pounds. Examination showed consolidation on the right side in the lower lobe; respiration increased; heart regular, but very rapid (115); frequent palpitations; no organic lesion. He has consulted various physicians. His treatment previous to the time he came to me consisted of cod-liver oil, guaiacol, creasote, expectorants, codein, and, lastly, hypodermic injections of morphin sulfate, $\frac{1}{8}$ grain every four hours, for the relief of the cough. I saw him for the first time on January 28, 1900. He had a constant cough and would expectorate large quantities of a mucopurulent discharge. I immediately stopped all tonic treatment, and put him on heroin, $\frac{1}{12}$ grain three times daily. He reported on February 6, stating that he felt a little improved, and that the cough was not so frequent, but complained that he could not sleep. Heroin, $\frac{1}{16}$ grain, was prescribed three times daily, and he was told to report to my office every day. The following shows the results of the treatment: February 7, cough slightly diminished; had slept better; pulse, 100. February 8, cough the same; appetite returning; weighs 101 pounds; pulse, 100. February 9, coughs very little now, with slight mucous expectoration; feels better than he has for five months; pulse, 95. February 10, only coughed twice during the day, and slept all night; pulse, 90. February 11, has little cough; complains of dryness of throat; reduced heroin to $\frac{1}{16}$ grain, twice daily; pulse, 90. February 12, dryness still persists; cough easier; no expectoration. February 13, cough has nearly gone; has no pain whatever; dryness of throat slightly perceptible; weighs 103 pounds; normal appetite; pulse, 85; gave him heroin $\frac{1}{16}$ grain twice a day and placed him on malt extract. February 16, improving daily; no cough; no dryness; weighs 103½ pounds; feels well; pulse, 85. Will go to Colorado in a few days. February 19. Before leaving for the West to-day he came to see me, and stated that he felt himself improving.

CASE 2.—Patrick L., aged 35, pulmonary tuberculosis, came to me for treatment November 16, 1899, with the following history: He had enjoyed excellent health until September, 1899, when he was taken with a chill, began to cough and expectorate yellowish-green sputum; appetite very poor; tongue coated; slight hemorrhages, and evening temperature of 100°. His father and mother died of consumption. On examination the following physical signs were found: Impaired percussion resonance, sibilant rales in left apex, crepitation in lateral area at base of left lung. Examination of sputa showed tubercle-bacilli. Treatment: Quinin, 6 grains, every three hours; atomization of turpentine vapor;

moderate chest exercise, diet of milk, eggs and wine. On November 20, 1899, the temperature (evening) was 101°; cough much worse; prescribed quinin sulfate, 10 grains every three hours, and mixture of tinct. opii 10 drops, mist. glycyrrhiz. comp., 1 dram every four hours. On November 28 his temperature was slightly reduced (100.6°), felt worse, and cough no better; weight, 114 pounds. Prescribed quinin sulfate 8 grains, and codein $\frac{1}{8}$ grain, every four hours. December 7, no better; same condition; appetite worse; prescribed creasote carbonate, 5 grains every three hours. I saw him on December 30; temperature, 101°; cough same; weight, 113½ pounds. Stopped all treatment and placed him on buttermilk, and poulticed his chest with flaxseed. January 15, the same condition existed; evening temperature, 102°; appetite poor and strength reduced. Prescribed anti-febrine, 6 grains, every four hours. January 17, temperature reduced to 100.4°; felt slightly better; weight, 113 pounds, but cough still persisted very annoyingly; sputum still showed tubercle-bacilli in large numbers. Continued same treatment. January 29, he presented himself at my office; appetite better; cough worse; temperature, 101°; said he felt stronger, nevertheless. Prescribed quinin sulf. 5 grains, and heroin $\frac{1}{8}$ grain, every four hours, with liberal diet. The results of the last prescription astonished me. February 5, he came to my office much improved; temperature, 99.4°; weight, 114 pounds; cough considerably lessened; now slept well at night, and stated that he had never felt so well for five years. Prescribed heroin $\frac{1}{16}$ grain, every six hours. February 10, reported to my office; temperature, 98.8°; cough much improved; has gained in strength, and weighs 115 pounds. Prescribed heroin, $\frac{1}{16}$ grain every six hours. February 12, evening temperature normal; appetite good; no cough at all; present weight 116 pounds. February 16, temperature normal; appetite normal; has not coughed for four days; has gained strength and weight daily (116½ pounds). Examination of the chest showed one or two rales, few crepitations at seat of trouble; increase of chest-movements. Has gone to work. Prescribed $\frac{1}{16}$ grain heroin twice a day. February 18, reports feeling splendidly. Examination of sputum showed no bacilli.

CASE 3.—Mrs. L., aged 39, married, chronic tuberculosis; came to my office on December 15, 1899, complaining of shortness of breath; has suffered for two years and has been gradually getting worse. Her trouble began with cough, but she does not bring up as much now as formerly. About six months ago she began to spit blood. She has lost weight; has no night-sweats, temperature, nor pain, except occasionally a slight pain in the right side which was first noticed in October. Family history is good. Physical signs reveal the following: Marked anemia, labored respiration, normal heart-beats, prolonged inspiration and expiration, bronchial rales in the smaller bronchi on inspiration and expiration; microscopical examination of sputum shows tubercle-bacilli; patient is cyanotic. Diagnosis, chronic tuberculosis with marked dyspnea. Treatment: creasote 10 drops, three times daily, with whisky; fluid diet. December 25, 1899, no better; continued treatment. January 2, 1900, no improvement; her cough is now very troublesome; also dyspnea; prescribed $\frac{1}{8}$ grain morphin sulfate, three times daily. January 10, 1900, no improvement; patient getting weaker and worse; prescribed quinin sulfate 5 grains, morphin sulfate $\frac{1}{8}$ grain, whisky, three times daily. January 16. Patient progressively worse; prescribed codein $\frac{1}{16}$ grain, digitalis $\frac{1}{16}$ grain, three times daily. January 30, 1900. Same condition; continued treatment. February 3. Patient very bad; prescribed heroin $\frac{1}{16}$ grain every three hours. February 4. No improvement; patient complains of dryness of throat and constipation; gave magnesium sulfate, continued heroin. February 6. Patient thinks she feels easier; dyspnea not so marked; continued heroin $\frac{1}{16}$ grain, three times daily. February 8. Patient again in bad condition; hectic fever, cough and dyspnea intense; very little expectoration; prescribed heroin $\frac{1}{16}$ grain and tincture digitalis 10 minims every four hours. February 10. No improvement; in fact, patient is worse. February 11. Same condition. February 12. Patient very low. February 14. Moribund. February 15. Death of patient.

In this case heroin was of no benefit; while at first it seemed to have relieved the dyspnea it failed entirely

as the remedy was continued. Nevertheless, I cannot take this case into very great consideration, as the condition of the patient and her death did not give sufficient evidence that the drug would prove unsatisfactory.

The remaining 10 cases all consisted of whooping-cough in children. I give below a condensed history of these cases treated with heroin.

CASE 4.—Jessie G. F., female, aged 3 years, whooping-cough, was brought to me on January 10, 1900. Nothing did good as far as internal remedies went; local treatment as inhalations, steam cabinet, applications to nasal cavity of silver nitrate availed but little. January 31, 1900 I prescribed heroin hydrochlorid $\frac{1}{16}$ grain, every four hours. February 4. Improvement quite marked; child sleeps better at night, is bright and takes an interest in affairs. February 7, improving nicely; gave heroin hydrochlorid $\frac{1}{16}$ grain, 3 times daily, in a dram of raspberry syrup; coughs about three times day. February 10. Improvement constant; child whooped once in 24 hours. February 12. No cough since yesterday; gave heroin $\frac{1}{16}$ grain morning and evening. February 14. Child gets along nicely; has only coughed once; this completes the sixth week of her trouble; and as the child seems much improved I discontinued treatment. February 16. Was called to see the patient at 10 P.M., and found her quite cyanotic and coughing severely; gave her hot bath and quinin sulfate, 1 grain. February 17. Child better, but whoops constantly; prescribed heroin hydrochlorid $\frac{1}{8}$ grain every 4 hours. February 18. Child has only coughed once since taking heroin; feels pretty good. February 19. Child better; cough has ceased. Heroin in this case gave results highly satisfactory. On February 14, I stopped the drug and coughing began as severe as before; when I began giving heroin again the symptoms and whooping subsided quickly.

CASE 5.—W. R., male, aged 11 months, whooping-cough; third week. Heroin $\frac{1}{16}$ grain was given three times a day; improvement noticed on second day. The cough ceased entirely in ten days. In this case heroin acted like a specific.

CASE 6.—J. R., female, 2½ years old, sister of above; whooping-cough following scarlet fever; second week of trouble. Heroin $\frac{1}{8}$ grain every four hours, eased the paroxysms and stopped the vomiting on the fourth day of the treatment; the whoop was reduced to one a day and one a night after taking the drug for 8 days. She sleeps well at night, has a good appetite. The dose of heroin was changed from $\frac{1}{8}$ to $\frac{1}{16}$ grain, three times daily. I saw her on February 17, and she was progressing nicely.

CASE 7.—T. M., male, aged 3½ years, whooping cough. On the second week I gave heroin hydrochlorid $\frac{1}{8}$ grain, every four hours. No change or improvement after a week, so that I discontinued heroin and introduced local measures with no perceptible results. On the fourth week I again gave heroin $\frac{1}{8}$ grain, every four hours; child began to improve gradually, and had an uneventful recovery in two weeks.

CASE 8.—B. L., male, aged 4 years, whooping-cough, with complications; cerebral hemorrhages. I exhausted the materia medica in attempts to relieve his condition. The paroxysms were pitiful to witness, and vomiting was incessant. At last I tried heroin hydrochlorid, $\frac{1}{16}$ grain hypodermically, every four hours; after three injections a change was noticed in his condition; he seemed somewhat relieved. The next day the boy felt a little better; he then developed bronchitis. Heroin $\frac{1}{8}$ grain was prescribed, three times daily. No other treatment was employed, and the boy made a complete recovery in three weeks.

CASE 9.—R. M., male, aged 2 years, whooping-cough. I prescribed heroin $\frac{1}{16}$ grain, three times daily, and local measures. No improvement occurred; the dose was increased to $\frac{1}{8}$ grain every four hours without any improvement. This case was not benefited by heroin or any local measure. In fact, heroin seemed to have aggravated his trouble. The child developed a pruritus of the anus also. Complete recovery took place without any medicine.

CASE 10.—X. M. P., male, aged 6 years, whooping-cough following measles. Heroin acted very well in this case, easing the paroxysms wonderfully. After the third day the child could sleep at night with only one or two whoops to

disturb its rest. It got well progressively in five weeks. In this case heroin only was employed.

CASE 11.—P. C., male, 6 years old; CASE 12.—T. C., 5 years old, and CASE 13.—W. C., female, 2 years old, all of same family, developed whooping-cough within one or two days of each other. Heroin was given in appropriate doses with the following results: Cases 11 and 13 progressed very nicely, and went on to recovery. In case 12, however, heroin had no effect whatever, but the child made a good recovery in seven weeks.

SUMMARY OF CASES IN WHICH HEROIN WAS EMPLOYED WITH RESULTS.

Case.	Name.	Age.	Diagnosis.	Duration of Treatment.	Results.
1	Joseph H.	28 yrs.	Pulmonary tuberculosis.	3 weeks.	Improvement.
2	Patrick L.	35 yrs.	Pulmonary tuberculosis.	3 weeks.	Improvement.
3	Mrs. L.	39 yrs.	Chronic tuberculosis.	12 days.	Patient died. Heroin gave some relief.
4	J. G. F.	3 yrs.	Whooping-cough.	3 weeks.	Recovery.
5	W. R.	11 mos.	Whooping-cough.	10 days.	Recovery; heroin acted as a specific.
6	J. R.	2½ yrs.	Whooping-cough.	10 days.	Improving.
7	T. M.	3½ yrs.	Whooping-cough.	15 days.	Recovery; heroin at first showed no effect.
8	B. L.	4 yrs.	Whooping-cough and bronchitis.	21 days.	Improving.
9	R. M.	2 yrs.	Whooping-cough.	18 days.	Child recovered; heroin did not act well in this case.
10	X. M. P.	6 yrs.	Whooping-cough.	15 days.	Improvement.
11	P. C.	8 yrs.	Whooping-cough.	20 days.	Improvement.
12	T. C.	5 yrs.	Whooping-cough.	20 days.	No effect whatever with heroin.
13	W. C.	2½ yrs.	Whooping-cough.	20 days.	Improvement.

These histories will do to show what the virtues of heroin are, especially in the treatment of whooping-cough. It is superior to anything we have for this trouble, and I am sure that it will prove a valuable addition to our materia medica; and in conclusion, when you have a case of pertussis, and you desire results, use heroin.

NOTE ON THE FREQUENCY OF RENAL CASTS WITHOUT ALBUMINURIA.¹

By C. F. MARTIN, B.A., M.D.

Assistant Professor of Medicine and Clinical Medicine, McGill University,

AND

F. B. JONES, M.D.,

Voluntary Assistant, Royal Victoria Hospital,

of Montreal, Canada.

THE presence of casts without albuminuria has been for many years recognized as not uncommon, though associated by most authorities with merely a few pathologic conditions. The diseases specially commented on in this connection are mainly: Acute poisoning, including alcoholism, icterus, arteriosclerosis, convalescence from ordinary nephritis, and pernicious anemia. Eichhorst and Senator, for example, regard the presence of casts in the urine as very uncommon when albumin cannot also be found, while Purdy, on the other hand, asserts that he has never yet met casts in the urine when likewise albumin could not be discovered at some period during the course of the malady.

The fact, however, that various writers take occasion

¹ From the medical clinic of the Royal Victoria Hospital, Montreal.

to note the conditions under which casts are found without albumin, implies the presumption that they are usually absent in most other conditions,—or, to speak more truly—that they have not been found. Von Jaksch, however, considering the subject, notes the frequency of hyalin casts in urine otherwise normal, regards their presence as nonpathologic and cites instances when casts have been found postmortem in perfectly healthy kidneys. He further states that casts of any other variety are extremely uncommon without albumin, except in conditions such as have been mentioned above. To state, however, that even hyalin casts occur in normal urine would seem to be practically begging the question, for the mere fact of their presence is of itself an indication that the urine is abnormal, and the best authorities agree that when-

tainty as regards the appearances found, we have noted that casts without albumin are found far more commonly in the urine than has been generally recognized.

In the examination for albumin the tests employed were mainly the boiling-test with acetic acid, and the so-called triple test with potassium ferrocyanid, and acetic acid. Whenever the slightest turbidity showed itself in the previously clear fluid, the specimen was regarded as containing albumin. In fact, one of us, (Jones) has found it of value to filter the urine after addition of the acetic acid, thereby obviating still more the possible presence of turbidity due to mucin or other ingredients. In other cases Heller's cold nitric acid test as modified by Ruttan was employed.

The urine removed was collected sometimes as a 24-hours specimen, or in other cases simply one portion of

ever casts exist, some lesion of the kidney, be it ever so slight, must be present. If casts are found in the kidneys in sections that show no alteration in the cellular structure, it does not preclude the possibility and probability that somewhere higher up where the casts were formed the secreting structures were pathologic.

A careful examination of the urine in the wards of the Royal Victoria Hospital has shown that in quite a variety of conditions casts have been found when no recognizable amount of albumin was present. It has been our custom as a matter of routine to examine the urine of each patient chemically by the ordinary tests and in most cases microscopically after duly obtaining a specimen by means of the centrifugal machine. Observing all due regard to the cleansing of our tubes, and absolute cer-

tainly as regards the appearances found, we have noted that casts without albumin are found far more commonly in the urine than has been generally recognized.

In the examination for albumin the tests employed were mainly the boiling-test with acetic acid, and the so-called triple test with potassium ferrocyanid, and acetic acid. Whenever the slightest turbidity showed itself in the previously clear fluid, the specimen was regarded as containing albumin. In fact, one of us, (Jones) has found it of value to filter the urine after addition of the acetic acid, thereby obviating still more the possible presence of turbidity due to mucin or other ingredients. In other cases Heller's cold nitric acid test as modified by Ruttan was employed.

The urine removed was collected sometimes as a 24-hours specimen, or in other cases simply one portion of

the specimens, though in every instance the same specimen of urine in which casts were found was simultaneously examined for albumin. In this way we were enabled to satisfy ourselves that even were it true that at certain periods of the day albumin was present (and this seemed in our cases very uncommon), that nevertheless under all conditions noted in our table the same specimen of urine which had showed an absence of albumin very frequently contained casts, not only of the hyalin form, but epithelial and granular varieties as well.

The subjoined statistical table, which covers merely the positive results from some 80 cases examined, will serve to illustrate in this primary note the frequency with which casts may be found in the urine when albumin is absent.

Under such conditions, then, it would seem difficult to estimate the true importance of casts in the urine, while it cannot but be believed that their occasional occurrence is devoid of the gravity in prognosis usually associated with their presence—*i. e.*, without other significant symptoms. This applies, at all events, to the hyalin and granular varieties; the epithelial casts, on the other hand, being more uncommon, and doubtless of more serious import.

Glancing over the conditions in which our few observations have been made, one is, perhaps, struck with the suggestion that irritating conditions are, after all, the main causes associated with the presence of renal casts—*i. e.*, just as bile acts as an irritant to the renal cells, so, too, would toxins, as they may occur in tuberculosis, pneumonia, typhoid fever, sepsis, etc., act similarly and render the cells of the kidneys incapable of performing their proper functions.

Further observations will be necessary to give satisfactory evidence as to the more common causes of renal cast-formation. That their presence, however, without albumin, is more frequent than is usually believed, seems evident from the examinations of patients, as given above.

A NEW FORCEPS FOR HOLDING SLIDES IN STAINING.

By THOMAS S. KIRKBRIDE, Jr., M.D.,

of Philadelphia.

Director of the Polyclinic Laboratories and Pathologist to the Polyclinic Hospital.

ALTHOUGH the staining of bacteria on the slide instead of on the cover-glass has become more and more customary, no attempt has been made, so far as I know, to avoid the staining and burning of the fingers which so frequently occur when the staining-solution is poured on the slide and heated over a bunsen burner. This is the more surprising since the method is daily carried on by almost every practising physician in staining for tubercle-bacilli, and by laboratory workers in staining that and other organisms.

The very simple forceps illustrated by the accompanying cut has been devised to obviate the accidents just mentioned. The slide is firmly held by the forceps which elevates it a short distance above the surface

upon which they rest, and as the slide slopes slightly downward toward the full end, the staining fluid does not tend to come in contact with the arms of the forceps. The elevation of the handle of the forceps makes it easy to lift from the desk without spilling the fluid, and in holding the slide over the flame the fingers are removed from danger of burning or staining. If a pair of the forceps is attached to each end of the slide it may conveniently be rested on a stand and left to heat slowly over a small flame.

The forceps has been made for me by Mr. S. Trenner, Philadelphia, to whom I am indebted for the trouble he has taken in carrying out my idea.

LEGAL AND JUDICIAL DISAGREEMENT AND THE SHORTCOMINGS OF MEDICAL WITNESSES.

By IRVING C. ROSSE, M.D.,

of Washington, D. C.

I AM aware that this is a hackneyed topic, and that of late expert medical testimony has been the subject of many gibes and much ridicule both from lay and medical sources. This is deservedly so, in view of mortifying exhibitions and the irrelevant matter often introduced at trials presumably for the purpose of promoting the ends of justice. Off the bench in the privacy of social converse, the judge will tell of his perplexity on hearing the disagreement of medical men on such occasions, although as a matter of truth and fact lawyers exist as a class only because they see differences in the same occurrences, and judges frequently disagree upon points apparently less recondite than the mental state of an alleged lunatic.

Error and contradiction are not confined to the medical profession alone. Even in such a simple matter as the appraisal of real estate for condemnation purposes there is wide divergence of opinion. In the question of lowering the topmasts of a ship to pass under the Brooklyn Bridge, 18 experienced persons, testifying before a commission a few years ago, gave as many opinions, no two of which agreed. In a railway litigation in which I was lately a witness a number of intelligent practical railroad men were asked on the stand how far a train of cars in certain given conditions would run before it could be stopped. No two of them agreed upon the distance, which they made to vary from a few yards to a quarter of a mile. A recent citation more to the point is that of the New York judges who were invited to a meeting of the New York County Medical Society to take part in the discussion of expert medical testimony. Like special pleaders, no two agreed and they differed widely upon the point at issue, to the merriment of the medical men in the audience, many of whom had reason to smart under the unjust criticism and severe stricture of the New York Bench.

In handling a theme of this kind, one feels inclined to recriminate with errors of judgment, differences of opinion, unfairness, and the like, and to cite innumerable cases showing the disagreements of judges and the fearful muddle that lawyers have made with plain matters of fact.

Pathology is a perennial subject, whether it relates to animal organism or the body politic. Just as it has in many instances thrown light upon physiologic subjects, so may the showing up and frequent bringing to light of certain morbid subjects and abuses help legal insight and contemporary science to bring about needed reforms. In the matter of forensic medicine, the questions affecting criminal responsibility or civil incapacity are largely those of diagnosis. That this diagnosis is often deplorably faulty, the records of many courts taken at random in various parts of the country will attest. Residents of Chicago may recall the case of a wealthy old man whose civil capacity being questioned, two general practitioners testified as to his mental soundness, because he showed accurate memory as to the events of his boyhood. Subsequent examination by an expert revealed the fact that he could not distinguish from one another nor tell the aggregate of three current pieces of money, nor could he add a column of six figures, or tell the time of day by a watch or clock.

Speaking of "Pseudo-Experts in Lunacy,"¹ Dr. S. Grover Burnett, of Kansas City, mentions the case of Myers, who, with premeditation, killed a man, robbed him, and divided the money. Yet the murderer was adjudged insane on the testimony of the general practitioner and was released. He went to the poor-farm for a few days, and then was allowed to go to his home "for fear that he might lose his mind if compelled to remain."

Persons disposed to animadversion may say that these incongruities are not surprising in the "wild and woolly West;" but when it comes to the "effete East," we should scarcely look for such anomalies of justice in the National Capital, where the attainments of the local profession are presumably at such a low ebb that it is necessary to call in outside talent to assist the Court.

At a recent criminal trial in Washington City, where the defense was epilepsy, an asylum superintendent of Philadelphia was employed as expert by the Government. The following gleaned from the stenographic report of the trial is a medicolegal contribution that speaks for itself.

Deposing to 45 years' experience, and that he had testified as expert in 19 capital cases, the witness was asked on cross-examination whether, as a matter of fact, he had not been quite often mistaken in his testimony before the Courts. To which he answered, "I don't know of a single case. If you can point out one, I will be very glad to know it."

"Q. 'Supposo,' queried the lawyer, 'in a case like this, involving the life or death of a fellow-being, you should tell the Court again and again that there were absolutely no physical signs of disease, and that after postmortem examination extensive evidence of disease should be found, would that, in your opinion, be a mistake?'"

"A. No, I don't know that it would. It might amount to a mistake if a man exercised his best judgment. I do not know of any such case. I don't believe that any such case has been found."

"Q. You found the defendant, Schneider, if you recall, in sound health, and without any symptom of disease at all—physical symptoms?"

"A. No, I didn't say that. *I never testified to that. He was in fair health and was feigning insanity. I only gave testimony in the case, the judges found the opinion.*"

(Aside from the extensive gross pathologic changes found at the postmortem of Schneider, which negatived the general conclusions of the "exhaustive" examination made by the experts for the prosecution, the Court record shows that the witness was one of the "three physicians of known eminence" who signed a report which says: "There seem to have been no serious physical changes whatever in his condition;" "An absence of deterioration;" "No corresponding appearance of physical deterioration of any kind;" and concludes with this sentence: "We would say, as the result of our personal examination of and study of the expert and lay evidence presented in Court, that it is our opinion that the prisoner, Howard J. Schneider, is not insane.")

This opinion, which the witness swears he did not give, also occurs in a supplemental report. Both were subscribed and sworn to before the Clerk of the Court, and in summing up the case Judge Hagner expresses relief to find that the Court's conclusions are in accord with the views of his experts.)

The doctor's testimony in the *Snell* case continues as follows:

"Q. What have you to say generally of epilepsy? May it exist and the seizures occur pretty much in the night?"

"A. Yes, I think in certain cases it often occurs in the night, and more frequently than in the daytime."

"Q. That is what you experts term nocturnal epilepsy?"

"A. They call it that. There is no significance in it. There are 30 (!) different forms of epilepsy."

"Q. And you think epilepsy in some patients occurs principally at night?"

"A. Yes, sir."

"Q. And you always thought so?"

"A. Always thought so."

"Q. Have you thought so for some years?"

"A. I have always known it to be so."

"Q. Did you ever under oath say anything like this (reading from a case record), in answer to a question from the Court, 'Are epileptic seizures more likely to occur in the night than in the daytime?' And you replied, '*There is no such form of epilepsy recognized as nocturnal epilepsy.*' Did you testify that way in the Taylor case?"

"A. I guess I did."

"Q. You are the author of this book? (Holding up a "Compend of Insanity.")

"A. Unfortunately, I am."

"Q. On page 86 I read, 'It would be advisable in such cases to watch the patient at night, as seizures are always more frequent at that time, and sometimes only nocturnal attacks occur.' How do you reconcile the conflicting statements?"

"A. It is unfortunate for a man to have written anything. The book was not written to be read in Court. It was intended for physicians."

"Q. The question is whether there are patients who have only nocturnal attacks?"

"A. I am perfectly willing that you put any interpretation you please."

"Q. Then you think you were in error when you alleged herein that sometimes only nocturnal attacks occur?"

"A. Perhaps I was; I make some mistakes."

"Q. That would be one error then?"

"A. Yes, I've no doubt at all of that. Dr. Rosse, over there, says the book is full of errors."

Despite extensive information on the subject by physicians and medicolegal writers, and the observation of neurologists, we are further informed that there is no such thing as hysterical insanity or witness would have heard of it in his 30 years' experience. He had never heard of Legrand du Saulle, nor of Campbell Clark's recent work on insanity.

Moreover, we are told by the witness that rheumatism is not a constitutional but a blood disease caused by uric acid, when the authorities are that it is a diathetic disease caused by lactic acid.

Attempts to explain the depressed fracture on the prisoner's skull led to several questions of cerebral localization and a description of the dimensions of the motor area. The witness, much nonplussed, said these were "too modern; you must get an expert for that."

"Q. But I thought you were an expert; we wish to get expert knowledge from you."

"A. I say I don't know anything about it. It does not belong to my department."

"Q. You examined the defendant's reflexes?"

"A. Yes."

"Q. What did the virile reflex show?"

"A. Don't know; that is a new reflex to me."

"Q. Did you test for headache?"

"A. No."

"Q. Did you use the Maunskopf test?"

"A. I did not apply that. You might put an expert on the stand for that."

"Q. I took you for an expert."

"A. This looks like a civil service examination."

A retarding pulse having been observed in the accused, the witness was asked: "What do you understand by a dirotic pulse?" To which he gave the fol-

² In the preface to this book the author expresses the hope that it may prove helpful to members of the legal profession, and that it may be understood by the nonprofessional reader.

lowing lucid explanation: "It is some indication of the heart's impulse, its condition, its operation, its contraction and expansion;" and he concluded with the astounding assertion that the defendant's epileptic seizures at the age of 23 "might have been due to dentition."

That the Government is not always happy in its medical selections we in Washington have frequent occasion to see. In the matter of Examining Surgeon for Pensions only a short time ago a former Commissioner of Pensions dismissed a competent and experienced man, an ex-army surgeon and a professor in a medical school, who had passed No. 1 at a civil service competitive medical examination, and substituted in his stead a homeopath, who was not only ignorant and illiterate, but had been an inmate of an insane asylum, and was arrested for petty larceny.

Such cases as the foregoing are not cited with a view to question the ability, honesty, or purity of anyone, but rather as a protest against the employment, on the one hand, of old men whose belated knowledge has not kept pace with the discoveries of the last 20 years, and on the other, of inexperienced persons unfamiliar with the newer methods and investigations of technical progress, and of their application to neuropathology; both classes bring ridicule and contempt.

Since the commitment of the New York reporter, Nelly Bly, and of a woman reporter in Washington who simulated insanity, there is, perhaps, no more ludicrous illustration of the entrapment of physicians to the amusement of spectators than that afforded lately at the trial of lawyer Creamer, an alleged parietic, who conducted his own case with considerable ability and even brilliancy. He cross-examined the Attorney-General at some length, and also submitted each of the physicians to rigid cross-questioning. As an inquisitor, who amused the courtroom at the expense of the physicians, the *Washington Post* of March 28 remarks:

He inquired with particularity as to the experience they had had in the line of their profession, and of each of them he asked: "Do you think that during this short time you have become qualified to testify in a case as an insanity expert?"

He further interrogated the two physicians as to what works on insanity they had read, naming several well-known authors. In conclusion he asked each if they had read "Oomah" on the same subject. The response was that they had. At this juncture Creamer burst out in a laugh, saying that there was no such work as "Oomah" on insanity, or on anything else; that he merely propounded the question to test the recollection of the physicians. He stated to the jury, amid great laughter in the courtroom, that the term "Oomah" was a figment of his (Creamer's) fancy merely and nothing more. In dismissing the two physicians he created an uproar in the courtroom by saying: "The kindergarten class is excused from further cross examination."

RHEUMATIC FEVER.¹

By J. NEWTON HUNSBERGER, M.D.,

of Skippack, Pa.

SOME authorities, Newsholme for instance, claim that this disease occurs in epidemics without regular periodicity; but I believe this multiplicity of cases met with at times is due entirely to atmospheric conditions; that is, long spells of damp, cool or cold weather with east or south winds certainly favor the development of the

disease. Late winter and spring is said to be the most favorable time for a recurrence of the disease, but I have observed more cases in autumn. Most of my cases have been between the ages of 25 and 35 years. I have rarely met the disease in young children. I have seen it most frequently in males because they are exposed to cold and dampness more than females. I have observed it in a small percentage of cases in young women a month or two after childbirth; these cases invariably occurring in women who had been gross feeders during pregnancy.

Acute rheumatism has been attributed to the entrance of micrococci into the blood; to a specific vegetable organism (*Symotosis translucens* of Salisbury) and to a miasm analogous to that of malarial fevers. Lyden has also found a diplococcus differing from that of pneumonia. But none of these theories has been proved conclusively. Gonorrhea and scarlet fever may occasion the disease.

Heredity plays a powerful and distinct role in the causation of this disease. Rheumatism runs in families and is passed on from parents to offspring just as strongly as is the tendency to gout or tuberculosis.

This tendency is most decidedly marked. In certainly 75% of my cases I elicited a history of acute rheumatism in near blood-relations.

The theory of J. K. Mitchell as to nervous origin has some followers, but seems to be somewhat vague. The most plausible theory of all is, that it is *metabolic* in origin; that is, that it depends on some morbid material produced in the system as the result of defective processes of assimilation. Prout considers this morbid material to be lactic acid or some combination of lactic acid, this acid acting as a distinct irritant to tissues especially of the serous variety. But previous to the formation of lactic acid there is a condition of the blood known as the uric-acid diathesis, which undoubtedly under certain conditions predisposes to attacks of acute rheumatism. This diathesis may be due to an overproduction of urates, but I believe is most frequently due to a lessened excretion of urates—more an error of excretion than of secretion. As an example of overproduction of urates I submit the following:

C. L., male, 32 years, farmer, robust, with a remarkably fine muscular development, had always been well. Always a big meat eater, had during the last year or two eaten regularly about 15 or more pounds of fresh beef a week, besides an enormous quantity of vegetables, pastry, etc. I might add that this voracious appetite was partly the result of a tapeworm, which I removed.

During January, while overheated from cutting timber, he was drenched with rain, and in a very few days was laid up with a most typical attack of rheumatism. He made a good recovery, but lost probably 50 or 60 pounds. I am treating a first cousin of this man at the present time for the same disease. He is of about the same build, age and temperament. The attack was brought on in about the same way as in the previous case.

On the other hand, to show the role that a lessened excretion of urates plays in the production of rheumatism I will report briefly:

A. K., farmer, 55 years old, is thin, nervous, inclined to be bilious, hard worker, exposed to all sorts of weather, and had never taken proper care of himself.

I saw him in an attack about 10 years ago. He had had a recurrence every spring for the preceding 4 or 5 years.

This man would have furious attacks. After the second attack I had seen him in, I put him on a good alkaline mineral water, having him use also large quantities of plain

¹ Read before the Montgomery County Medical Society, April 11, 1900.

water, with the result that he has had no return of rheumatism for 7 or 8 years. I may add I put him on this treatment after the holidays yearly. This man's daughter has had two attacks of acute rheumatism and is subject to periodic attacks of headache.

Uric acid or lithic acid does not exist in the body as such, but exists physiologically in the blood and urine as a quadriurate, a superacid combination. As uric acid exists normally in the body as a quadriurate any change from this state is pathologic, and this may take place in two ways, viz.: either the quadriurate is decomposed and uric acid set free, tending to the formation of calculi; or the quadriurate is evolved into the more stable biurate, which is deposited into the tissues, causing, gout, rheumatism, and that condition known as the uric-acid diathesis. In perfect health the uric acid which circulates in the blood as the quadriurate is removed by the kidneys unchanged, but in the gouty or rheumatic state, either from defective kidney action or faulty digestion and assimilation, the quadriurate lingers unduly in the blood, being transformed gradually into the almost insoluble sodium biurate, which resists removal by the kidneys, and the latter, as the result of undue stimulation, lose to a certain extent their powers of excretion. Under these new conditions sodium biurate continues to accumulate in the blood up to a certain point when it is precipitated in the crystalline form in the joints and through the system, tending to bring on attacks of gout or rheumatism under certain conditions. This is a common condition and one frequently overlooked. Dr. Boardman Reed says regarding it:

In my laboratory, out of many hundreds of urinary analyses made during the past year, albumin was present in only two cases, and sugar in one. On the other hand, in fully one-half the cases indican in excess was found, and in a considerable portion there has been revealed also an abnormally high total acidity, made up largely of uric acid and the products of fermentation. Patients with overacid urine are apt to be sufferers from intestinal indigestion, constipation, rheumatism, neuralgia, headache, or insomnia, and often several of these ailments, as well as a variety of nervous symptoms. Not till the excessively acid condition of the system has been removed by improving the digestion, by alkaline diuretics, and an appropriate diet, including an abundance of pure water, do the patients make any substantial improvement in health.

It is this very condition, common enough as we all know, that gives us the key to the proper treatment of acute rheumatism.

The changes found in the joints on postmortem examination are slight. Synovial membranes are hyperemic, and there is more or less effusion of fluid into the cavities of joints and surrounding tissues. This fluid may be ordinary synovial or diluted with serum containing blood-discs and pus-cells. There is rarely suppuration or ulceration of the cartilages.

The symptoms of acute rheumatism are so well known to all of you, that I shall not attempt to describe them, but shall merely refer to the peculiar way this disease has of making a complete circuit of the joints of the body, during the disease and sometimes in fact making three or four heats out of it.

The temperature in ordinary cases is not particularly high, 102°, 103°, sometimes going as high as 104°; but the profuse perspiration that occurs is nature's attempt to eliminate the urates and acids already in excess, and is not the result of medicine, as some physicians like to tell us. I repeat, this profuse sweat usually takes care of any excessive temperature. I have had very little experience with serious heart-complications, except in

one case, due to the administration of sodium salicylate, to be noted later. The urine is always high colored in the early stages of the disease, reduced in amount, and exceedingly acid, but with proper treatment the urine soon clears up and increases in amount.

Four indications must be met in the treatment of acute rheumatism: 1. To prevent fresh chilling of parts. 2. To keep affected parts at rest. 3. To attempt to modify condition of blood and neutralize the irritant action of the rheumatic poison in joint and other serous tissues. 4. To prevent, if possible, inflammation of the endocardium and pericardium. I might also mention to relieve pain, but with the following treatment I have had so little trouble with pain as not to require special mention.

To prevent chilling of parts, have affected joint well anointed with olive or some other bland oil. Wrap the parts well with two or three layers of absorbent cotton and retain in situ with a few turns of a roller very lightly applied. Cold, blisters, or irritant lotions are absolutely contraindicated for reasons that should be apparent to any thinking physician. I would say further that as the inflammation subsides in a joint, good, thick flannel should be substituted for the cotton. I have flannel bags made for the hands—in fact, mittens which allow the patient the use of his hands without risk of chilling.

The patient should always lie between good, woolen blankets, and in a room well ventilated, but kept at a temperature of 75 or 80°. Good blankets and a hot, well-ventilated room, I consider of the highest importance. It is well to have the patient wear a flannel nightdress open down the front, and with slit sleeves held together with safety pins. If possible, the patient's body, not the affected joints, should be thoroughly rubbed with a rough towel two, three, or more times a day, and once a day bathed lightly with alcohol. It is needless to add the patient should have a good, soft, but somewhat firm bed.

According to Chambers the tendency to endocarditis and pericarditis is much reduced when the patient is kept between blankets.

Fixation of the joints can be easily accomplished by binding them to small, specially made pillows or cushions having in their centers pasteboard or some allied substance.

The third indication, to modify condition of blood and neutralize irritant rheumatic poison, can be best accomplished by a proper diet, ingestion of great quantities of water, and the administration of potassium carbonate. The diet should consist in part of milk, always diluted if you get it pure, ice-cream, stewed fruits, canned fruits, and some of the farinaceous foods. Oranges and lemons when desired. No tea or coffee, positively no beef extracts, which are after all nothing but concentrated urea, and absolutely no meats. A good alkaline mineral water should be freely used in sufficient quantity to produce one or two soft stools a day. If unable to get this action then administer magnesium sulfate, well diluted, in sufficient amount to keep up a good action of the bowels. This is an important part of the treatment.

And then pure water, not ice water, but iced water when you can not procure good, fresh well-water. Don't boil the water. Never give less than a gallon a day and as much more as you can coax, scare or bribe your patient into taking.

If I were asked what one substance met the most

indications in the treatment of acute rheumatism I should most unhesitatingly answer *water*.

It may be necessary to sometimes flavor the water with some harmless substance when your patients rebel, but usually they take to it kindly.

Medicines have little control over the duration of this disease, most cases running from 2 to 6 weeks, or until inflammation subsides. There is no doubt, however, that much can be done to modify its course; and as a modifier there is no drug comparable to potassium carbonate. This is an exceedingly soluble salt, must be given well diluted and, unlike the bicarbonate of potassium, is not irritating to the digestive organs. In fact, it has a particularly soothing effect on an irritable stomach, and is an excellent remedy to relieve vomiting, given in from 1 to 2 grain doses every hour or half-hour.

In acute rheumatism it should be given in from 10 to 15 grain doses every 2 hours until an amelioration of symptoms, and after that every 3 or 4 hours during the entire course of the disease, increasing or diminishing the dose as may be indicated. It acts best when given on an empty stomach, and never should be given immediately after eating. It should be freshly prepared daily.

It has the power of diluting the blood; the amount of urine is markedly increased and rendered alkaline. Free uric acid is converted into soluble urates and speedily eliminated. Its action is rapid. It relieves pain quickly, and if continued regularly seems to modify the inflammatory process. I wish to say regarding pain, that my cases do not average more than 3 small Dover's powders during the entire course of the disease. I never give morphia.

Potassium carbonate has a sedative action on the heart, and under this treatment cardiac and arthritic complications rarely occur; it is the drug to use when any cardiac complication is suspected or expected. Personally, I have never had any trouble with heart-complication since using this treatment, nor have I had any thickened or stiff joints remaining as a sequel.

The fourth indication for treatment—that of preventing endocarditis and pericarditis—can be best met by the treatment I have outlined. I have not spoken about hyperpyrexia, or cardiac affections when they occur, pulmonary or cerebral complications, or of the nodules, for these conditions are rare in the average physician's practice.

Before closing, I wish to speak of a drug which I believe has done infinite mischief in this disease; not only do I believe it to be harmful, but absolutely contraindicated. I refer to salicylic acid and its various combinations.

Fairly large doses, such as are usually recommended in acute rheumatism, reduce blood-pressure and most decidedly weaken the cardiac beat. More than that, the drug has a cumulative action, and some cases of death due to cardiac weakness can easily be traced to a long-continued use of the drug. It is true that in rheumatism you may produce a fall of temperature, by the salicylates, but this fall is always accompanied by a profuse sweat, which is very exhausting. Its antipyretic action being due to a depression of the central nervous system, it is, in fact, a form of shock, and in no way does it tend to eliminate the poison of the disease or modify its course, the temperature usually rising rapidly after sweat is over. It is not a reliable antipyretic, an instance being recorded in Foster's Thera-

peutics in which sodium salicylate sent a temperature of 101° F. up to 107° F. Its action on the kidneys is not what a proper comprehension of the disease demands. It even at times tends to diminish the amount of urine secreted and may bring on hematuria and albuminuria.

Germaine Sée observed no change in the nitrogenous elements in the urine after the use of the drug in health or in disease. It certainly does not increase the elimination of uric acid and thus lead to cure, while it does increase the liability to relapse.

In the early years of my practice I used the salicylates in rheumatism because it was said to be the proper treatment. I used it for a year or two with rather unsatisfactory results, and recall one case whose end was undoubtedly hastened by its use. This was a somewhat mild case of rheumatism and I spent a bad half-hour at her bedside after the third or fourth dose had been taken. I thought she would die, but she responded to stiff stimulation and made a very slow recovery, the heart never regaining its tone. There was some endocardial trouble, but not sufficient to keep it acting so badly.

The case drifted out of the neighborhood and in less than a year I heard of her death, somewhat suddenly, I was told, of heart disease. The case was in a middle-aged woman who had enjoyed fairly good health, except for troubles attributed to an excess of uric acid.

Silver Nitrate Applications to Diseased Uterine Mucosa.—James Stirton (*Glasgow Medical Journal*, June, 1900) advocates the silver salts, particularly silver nitrate deprived to an extent of its water of crystallization and somewhat diluted by the addition of some other nitrate, preferably potash, in the attempt to restore healthy action to diseased uterine mucous membranes. This combination is not caustic in destructive effect upon the mucosa, being nothing more than a rapid oxidizer; the hemorrhage, which sometimes ensues 3 or 4 days after the application, he considers distinctly beneficial. He deprecates the generally growing use of the curet instead of the local applications at one time so popular, on the ground that this is the employment of mechanical means used in the dark on a surface whose pathologic condition is comparatively an unknown quantity in its entire extent. There is great risk of scraping off a thicker layer than would be beneficial, thus doing serious mischief to the physiologic action of the organ during pregnancy. He has often seen abortions which were clearly referable to contractions after cicatrization when excessive cureting had been done. A reaction will come about soon in favor of the older method. [M.B.T.]

When to Tie the Umbilical Cord.—James Stirton (*Glasgow Medical Journal*, June, 1900). Vigorous circulation through the funis implies defective circulation through the lungs or nonestablishment of this function; tying the cord under these conditions is immediately followed by complete arrest of the flow of venous blood through the umbilical arteries, and as these trunks are large, the shock to the circulation, or rather the sudden arrestment of the blood through the pelvis, in the first instance, is followed by a congested condition, which tells mostly on the bladder, as the anatomic relationships clearly indicate. The liver is secondarily affected, since the supply of arterial blood from the umbilical vein is suddenly cut off before oxygenation of blood through the lungs has been established, and congestion ensues, with often attendant jaundice. The brain suffers, although less frequently, but convulsions may ensue owing to the blood circulating through it being less oxygenated than is necessary to its due nutrition. Due closure of the foramen ovale of the heart is delayed, and irregular action of the heart induced in after-life, under the influence of slight shocks to the system, such as would not have had any appreciable effect on it in its ordinary condition of health and action. [M.B.T.]

VOL. VI, No. 11

SEPTEMBER 15, 1900

\$3.00 PER ANNUM

The Relation of the Courts to Administration of Sanitary Laws.—Persons interested in sanitation often think that a desired end is attained when a law has been passed making certain requirements. That is indeed the first step, but it is only a step. It must be followed by the appointment of an intelligent and earnest health-officer, having all the instincts of a combined diplomat and fighter. And this man's efforts may succeed or fail according to the amount of cooperation he can obtain from the community at large and from those specific agents appointed by it, viz., prosecuting attorneys and judges. An old maxim has come down to us from past centuries to the effect that the "king can do no wrong." We sometimes laugh at the condition of mind and morals that could have led any large number of people to accept such a dictum. It is a fact, however, that we still preserve and act upon the spirit of the old maxim at this time, substituting for the one infallible person a whole class of men whom we call judges and who are supposed by the laws to be incapable of doing wrong. The most nondescript, shameless and vile character, publicly recognized as such when simply a member of the bar, becomes before the law incapable of error when he is by the misfortune of politics or the favor of the appointing power elevated to the bench. To these modern infallibles are left the decision, in common with all other questions of importance, of the propriety, wisdom or safety of measures necessary to be adopted for the public welfare from a sanitary standpoint. To say that judges are simply human suffices to call attention to the fact that they may be either good or bad, ignorant or wise, faithful or unfaithful in the performance of their duties. Criticism of them and of their judicial acts should therefore be limited to instances of errors committed; praise should be limited to instances when duty is well and faithfully performed. But in any event we have a right to insist that that mock divinity which has so long hedged them about shall be torn aside and that the bench shall submit to the same process of learning to which all the rest of the world has submitted and by which it has certainly profited.

Careless prescription-writing is an evil to which some physicians are said to be subject. It may be looked upon as an evil, but it is certainly more—it is criminal! Worry, care, oversight, overwork, and every-

thing else that may be advanced, are no excuse for the offense. Were it not for the check placed upon such prescription by the pharmacist no end of trouble might result. Even as it is there are doubtless many fatalities which may be charged up to careless prescription-writing.

The Growth of Hair and the Menstrual Function.—Many of the medical profession in France seem to have become infatuated with *médication cacodylique*, i. e., the administration of sodium cacodylate, an organic arsenic preparation which apparently possesses remarkable alterative properties. Thus, for example, Gautier at a recent session of the Académie de Médecine made a report of the case of a young woman in whom the use of sodium cacodylate produced a more abundant growth of hair on the scalp, a disappearance of pigmentary spots, and a noteworthy regularity and a freer flow of the menses. This observation led him to study, in collaboration with Donser, the disassimilation of iodine and arsenic in the system. The arsenic contained in the menstrual blood was first estimated. Computation in four cases gave an average of .28 mgm. of arsenic per kgm. of blood. As about 500 gm. of blood is discharged during a catamenial period, the amount of arsenic eliminated at each menstruation is 0.14 mgm. This corresponds practically to the entire quantity of arsenic normally contained in the thyroid gland of a woman. The iodine estimations showed that the menstrual blood contains four times as much as the normal blood. Both of these substances—the iodine and the arsenic—are furnished by the thyroid gland. Gautier claims to see a relationship between the growth of hair and the menstrual function, and states that among nuns who cut their hair menstrual troubles are frequent, especially if the cutting of the tresses coincides with the menstrual period. Many women, he states, have noticed certain peculiarities in their hair, by which they recognize the approach of the menses. In the male sex the hair continues to grow at puberty, while in the female, in which puberty corresponds to the establishment of the menses, the growth of hair is arrested at that period. During pregnancy certain alterations take place in the skin which Gautier believes are prevented by arsenic. The cacodylates have also a favorable influence on the pigmentations of the skin seen in tuberculosis. Gautier's conclusions

regarding the value of arsenic were challenged by Fournier, who pointed out that arsenic had been of no value whatever in prurigo gestationis, the only remedy for which is accouchement; but Gautier contended that the action of organic arsenic compounds, like sodium cacodylate, could not be compared with the action of other arsenic preparations. Gautier's theory is interesting; but if it were not supported by a man of his standing, it would, no doubt, be considered far-fetched and fanciful.

Births and Deaths in German Cities.—U. S. Consul General Richard Guenther, at Frankfort on the Main, sends to the State Department a report on the statistics of large German cities. These statistics are compiled in Munich and contain tables for 1899 from 74 cities.

At the head stands Berlin, with a population of 1,800,000; then Vienna, with 1,600,000; Hamburg, 684,700; Munich, 452,000, and Leipzig, 430,600. Regensburg with 43,000 closes the list. The 74 cities have an aggregate population of 12,750,000, and return a total of 418,633 live births and 258,524 deaths, an average birth-ratio, therefore, of 32.8 and an average death-ratio of 20.3.

The ratio of births per 1,000 inhabitants was largest at Königshütte in Silesia, with 62.03. Altendorf was next with 51.1, and Potsdam was lowest with 20.9. For 10 cities the ratio is between 50 and 40, for 48, between 40 and 30; for 14, between 30 and 20. The ratio of still-births was highest at Vienna—6.2; lowest at Königshütte—1.8. Illegitimate births were highest at Vienna—32.7; lowest at Reinscheid—1.7. The ratio is very low in all the cities of the Rhine and Westphalia, nowhere more than 7 per 1,000. It was high (20 and more) at Dresden, Würzburg, Metz, Strasburg and Munich, the latter city, with 27.0, coming next to Vienna. The death-ratio was highest at Königshütte, with 29 per 1,000, and lowest at Schönberg, near Berlin, with 12.9. High ratios were shown in the following cities—Bochum, Regensburg, Elbing, Fürth, Duisburg, Stettin, Halle, Breslau, Chemnitz, Danzig, Posen, and Königsberg—*i. e.*, 24. A low ratio—15.4—was shown by Charlottenburg and Zurich. Of the remaining 58 cities 28 show a higher rate than 20, and 30 cities a lower one. It is noteworthy that the highest birth-rate as well as the highest death-rate was shown by the comparatively unknown town of Königshütte. The reason for this is not apparent.

Infant mortality was especially great, when compared with the number of live births, at Rixdorf, near Berlin, with 50; also at Harburg, near Hamburg, with almost 50. In a few other cities it was as high as 45. It was lowest at Aix-la-Chapelle, with 23.

The most conspicuous causes of death were tuberculosis, inflammation of the respiratory organs, diseases of the heart, catarrh of the intestines, and dysentery.

Typhoid fever was nowhere remarkably prevalent; most so in Berlin and Vienna. The ratio of suicides in 10,000 inhabitants was highest, with 4 each, at Hamburg, Gera, Brandenburg, Leipzig and Breslau.

Other deductions from the tables refer to the various causes of death, and are not specially significant.

Some Definitions of the Word "Crank."—One of the most interesting phases of linguistic studies pertains to the changes in the meanings of words which, as we know, may become better or may become worse. A word may even come to mean precisely the reverse of what it did to a previous age. Deterioration is the usual rule. The term *crank* is a recent coinage, but until now has been uniformly applied to those peculiar people whose fads or whims have not been held worthy of imitation, but rather of contempt. They were thought below normality in intellect and ability. At present among medical men one hears the word applied to those who show very different characteristics, and the fact indicates that the word is undergoing a decided change in significance. A man of character would not call a characterless man a crank, simply because he is a sharper, but the reproachful word is frequently used by the characterless to denote a physician of exceptional honor and integrity. We recently heard a health-officer who has shown heroic zeal and unselfishness in the administration of his office stigmatized as a health-crank. He had no hobbies, except to protect the community from infectious diseases. In all such cases the secret motive is to excuse oneself for lack of professional or ethical spirit by calling the better man by this opprobrious name. One who hates medical politics is dubbed a crank by the politician. The schemer for office thus appears to justify himself. The medical editor who sells his columns to the reading-notice man naturally calls the better journalist who refused to do this a crank. Those who exhibit zeal for professional good, who criticise professional abuses are, by the fact of their existence, a standing rebuke to those who never had or who never obeyed an ideal of duty, and they are naturally anxious to hide their shame by crying *crank!* It is an old bit of psychologic legerdemain which only fools the fool. When these feel the sting of conscience they whisper *Devil, Devil!* or hunt up a scapegoat. It will soon be that all tricksters will call all honest men cranks, and then a new word will have to be devised for the old time fad-rider. All medical reformers are cranks to those who compound with sins they have a mind to, so that soon the word *reformer* will be a useless synonym. It is time that we should have a word to designate all those cunning folk who rid themselves of obligation by sneering at those who believe in duty and labor for professional progress.

Vital Statistics of the State of Maine.—Dr. A. G. Young, Registrar of Vital Statistics of the State of

Maine, has just issued his report, unavoidably delayed, for the year 1898. The report is a very full one, replete with interesting figures, and is an admirable example of the statistician's art. It does great credit both to the State and to the author. If every State in the Union issued such a complete report, we should soon have a body of statistics for the whole nation that would be of incalculable value in the future as a basis for most important studies in some departments of sociology. We have but limited space here to dip into these many pages of figures, but we can at least bear witness to the fact that Dr. Young has the talent for making mere tables of figures tell an interesting story. Among the important facts illustrated is the decrease in the death-rate from tuberculosis in the State at large. This decrease has been steady for the seven years (1892-1898) during which these reports have been issued. Thus in 1898 there were 331 fewer deaths from this cause than in 1892, and 107 fewer than in 1897. During this period the population of Maine has undoubtedly been increasing, so this decrease in the prevalence of tuberculosis is still more significant. In commenting on this satisfactory showing, Dr. Young says that the reasons for this falling-off in the death-rate from consumption are probably more than one, but the principal reason, he thinks, is found in the fact that the people of the State have acquired an intelligent understanding of the disease and its perils. They have been taught that tuberculosis is an infectious disease and therefore a preventable one. This knowledge has been disseminated by the State Board of Health, which in 1889 issued the first edition of its circular on the prevention of consumption. This circular has been issued repeatedly in large editions and has been distributed in every town by local health-boards and even by the clergy from their pulpits. This propaganda has been helped on also by the press, so that Maine has been now for twelve years the scene of a campaign of education on the subject of tuberculosis. This certainly is an interesting fact and well worth noting.

The following figures are important. The population of the State, according to the census of 1890, was 661,086. The number of births in 1898 was 21 less than in the preceding year. The birth-rate for the State was 21.89. There were 187 less marriages than in 1897 and, we regret to say, there were all told 764 divorces; an increase over 1897. The divorce-rate has been increasing since 1892. These figures are not altogether flattering to Maine, for with decreasing marriages and births, and increasing divorces, the State has a slightly blasé look. Hard times preceding 1898 probably account, however, for the lower marriage-rate. On the other hand, the number of deaths in 1898 was 280 less than in 1897, and the death-rate for the whole State was 16.57—a highly satisfactory showing. There were 6 homicides and 56 suicides. Seven persons, whose deaths were recorded, had reached the age of 100

years, but some of these cases were not well authenticated.

Dr. Jacob M. DaCosta.—Dr. DaCosta, than whom no one has done more to make and to keep Philadelphia the medical center of the Western Hemisphere, is no more. Coming to this country an unknown youth from a foreign land, he rose by his labors to be a popular physician, a revered teacher, and a trusted consultant, and became so identified with the institutions of learning and the traditions of this city, that it seemed as if he had always lived here.

Although graduating from the Jefferson Medical College at the early age of 19 years, he had previously found an opportunity to acquire a classical education of rare completeness. His knowledge of the foreign languages at a time when such knowledge was far less common than it is at present, enabled him to keep pace with the progress of medicine in European countries. This widened his horizon and stimulated his clinical studies. During the Civil War, when he had scarcely attained his thirtieth year, his observations on the heart of the American recruit were not only masterly but epoch-making, and secured him at once a name both in this country and abroad.

Realizing the value of pathologic studies, he gave in his earlier years much attention to morbid anatomy; indeed, he never lost his interest in this branch of science and watched an autopsy on a case in which he had been interested with all the zeal of one belonging to a younger generation. Only a few weeks ago he discussed with keen interest the results of a necropsy in an obscure case, and endeavored to explain step by step the clinical symptoms in the basis of the morbid lesions.

When but 24 years old he assisted in the organization of the Pathological Society of Philadelphia, and was its president from 1864 to 1867.

Dr. DaCosta was not a man of visible enthusiasm; he was not demonstrative. Yet under his calm, almost passionless exterior he harbored an intense, unflagging zeal for his profession, and gave to it practically all his time. He utilized, better than most men, private and hospital practice to develop that clinical instinct—the *esprit clinique*—which was the foundation of his fame, and made him the greatest clinical teacher of his day. Medical cases represented to him not isolated experiences; he could recall them at the opportune moment and possessed the power to generalize from them—a rare gift. As a teacher he exhibited a marked individuality and stamped his influence indelibly upon his hearers. He was fond of arriving at a diagnosis by exclusion, and his vast knowledge of medical literature and enormous, well-classified experience, made his results often remarkable.

His book on medical diagnosis, which has passed through many editions and has been translated into a

number of foreign languages, bears the imprint of an original mind, and will forever be looked upon as a pioneer and exemplar. In his journalistic writings he showed his greatest powers—few had the gift of selecting as interesting and timely topics, or of presenting them in as clean-cut and entertaining a manner. There was something of the judicial in the calmness of his reasoning on clinical problems.

Dr. DaCosta was not an experimenter. His contributions to medical knowledge were based on bedside and postmortem observation; he thus approached the great English clinicians of the first half of the nineteenth century, or the illustrious representatives of the French school in its best estate.

The medical profession of Philadelphia has delighted in honoring him: he was president of the College of Physicians; and national honor came to him in the presidency of the Association of American Physicians.

As a consultant, he held a supreme position in Philadelphia—he was par excellence the physicians' physician. In the sick-room he was always cautious and gave his opinion in a quiet tone, entirely devoid of dogmatic quality.

His death is a shock to Philadelphia; a grievous loss to the medical profession, not only of the city, but of the Nation. But his work will live!

English Factories and Workshops.—The annual report of the Chief Inspector of the Factories and Workshops, for 1899, has been published by the Home Office in England. The list of casualties shows an increase over like schedules for 1897 and 1898. This is accounted for by the increased industrial activity during the past year. The number of accidents certified to for 1897 were 15,985, for 1898 were 19,227 and for 1899 were 22,771; during the last year mentioned there were 871 fatal accidents, 858 of the victims being males and 13 being females. From these figures it would appear, fortunately, that the percentage of women employes engaged in dangerous occupations is very small. A less pleasing feature of the report shows that the number of accidents to children has increased.

The act requiring compulsory notifications in factories and workshops handling dangerous and poisonous materials has proved its efficacy by reducing the number of cases of poisoning and death resulting from these substances. This is particularly true of lead-poisoning, and necrosis from phosphorus-poisoning. It appears that the various strict measures introduced, under compulsion, to minimize the dangers to operatives have not only secured the desired result and brought safety where danger once prevailed, but in addition have induced manufacturers to substitute other means and methods which are not dangerous. Thus inventive minds have been stimulated to further research and

new discoveries. This is shown by the fact that match-factories may now dispense with the use of yellow phosphorus, that glaziers have adopted new methods for using lead in glazing, and that in the silvering of mirrors a change in method and materials has been introduced which prevents much of the old-time mercurial poisoning.

The report shows that anthrax, coming from the handling of wool, hides, pelts and horsehair, is more common than formerly. The danger to the operatives depends much on the source whence the materials came. Those coming from China appear to contain the greatest element of danger.

A peculiarity of the English system is that in case a medical practitioner is called to attend a person suffering from poisoning by lead, phosphorus, arsenic, or from anthrax, which can be traced to a factory or workshop, he is required to report the same, together with the name and address of the patient, and the practitioner in turn receives a fee of 2s. 6d., paid by the Home Office.

Conservative Operations on Ovaries and Tubes.

—Burrage (*American Journal of Obstetrics*, August, 1900), from an analysis of 85 cases, deems the following conclusions are justified: 1. It is advisable to do conservative operations in all cases where the ovaries and tubes are not hopelessly diseased in all parts of their structure, except on patients who have pronounced gonorrhea of long standing, and on the rare cases of malignant disease. 2. When a patient is near the menopause (over 35 years of age) and has ovarian or tubal disease of any considerable degree of severity, it is generally wiser to perform complete removal, with or without hysterectomy according as the uterus also is diseased or not. 3. In cases of well-marked gonorrhea of long standing, especially if the patient is constantly exposed to reinfection, if both tubes are seriously diseased and closed, total removal with or without hysterectomy is the operation of choice. 4. In certain cases of this class where the patient thoroughly understands the likelihood that another operation may be necessary at some future time, and wishes to take the chances in the hope of preserving the function of menstruation, conservative operation is permissible. 5. If one tube is patent and healthy in appearance and there is enough healthy ovarian tissue to preserve, a conservative operation ought to be performed even in the presence of gonorrhea. 6. With present methods of performing resection of the tubes, if both tubes are found closed at the time of operation subsequent pregnancy is not to be expected. 7. In severe grades of inflammation of the appendages, irrespective of causation, if the ostium abdominale of one tube is patent, the prospect of subsequent pregnancy after the preservation of a portion of ovary is about 1 in 4½, or 23½%. 8. In the less severe grades of inflammation, under similar conditions of tube and ovary, the prospect of subsequent pregnancy is about 1 in 2½, or 44%. 9. In women who have borne children, in both classes, subsequent pregnancy may be expected in 35%, whereas in the previously sterile it may be looked for in only 5%. 10. If it is necessary to remove both ovaries it is of no advantage to preserve any portion of tubal tissue; but, except under the conditions just enumerated, some ovarian tissue should be preserved in every case. [W.K.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Epidemic in York County.—An epidemic in the form of dysentery, from which 17 deaths are reported, is prevalent near Yocumtown, Pa.

Violators of Pure Food Laws.—Arrangements have been made at Harrisburg for the trial of the alleged violators of the oleomargarine and pure food laws. Over 50 true bills await the court's action.

Fifty Thousand Dollars for Wife's Affections.—Dr. J. H. Berlet, of Philadelphia, has brought suit against his assistant, Dr. George W. Betz, to recover \$50,000 damages for the alienation of the affections of his wife.

Living with Broken Neck.—James Lavale, of Erie, Pa., is paralyzed from the shoulders down and has his neck dislocated besides, the result of a plunge from a bridge. An x-ray examination shows that there is a chance for his recovery.

New Jersey State Board of Health.—George P. Olcott, of East Orange, has been appointed to succeed the late Dr. Gauntt as a member of the State Board of Health. It was the wish of the other members of the Board to have associated with them a sanitary engineer, and Mr. Olcott fulfils this requirement.

Building for Nurses Needed.—Secretary Biddle recently inspected the charitable and penal institutions of Harrisburg, Pa., and made a very favorable report. He recommends a new and separate building for the nurses employed in the Harrisburg Hospital. At present the nurses must spend their time off duty in the institution.

Pure Food Case Continued.—The case of Burns & Metzger, spice manufacturers, of Philadelphia, who were arrested recently by order of the State Dairy and Food Commissioners, came before Magistrate Stratton for a hearing. The charge against the defendants was a violation of the pure food law. The firm is prosecuted upon the information of an expert chemist, who reported that he had discovered several mixtures in the pepper and adulterations in the spices. The case was postponed until later.

Vital Statistics of Philadelphia for the week ended September 8, 1900:

Disease.	Cases.	Deaths.
Total mortality		370
Inflammation of appendix 4, heart 1, brain 11, bronchi 6, kidneys 9, lungs 1, larynx 1, liver 1, lungs 26, prostate gland 1, spine 2, stomach and bowels 19, uterus 1, veins 1, nerves 1		85
Lungs—tuberculosis of 45, congestion of 2		47
Marasmus 26, inanition 7, debility 7		40
Cholera infantum 29, morbus 1		30
Apoplexy 14, paralysis 7		21
Bright's disease 5, uremia 13, diabetes 2		20
Heart disease		16
Convulsions 13, puerperal 1		14
Carcinoma of breast 2, liver 1, stomach 6, uterus 2, sarcoma of jaw 1		12
Old age		11
Diphtheria	95	11
Brain—dropsy of 2, softening of 5		7
Casualties		6
Anemia		5
Typhoid fever	75	4
Diarrhea 2, dysentery 1		3
Septicemia 2, pyemia 1		3
Suicide—laudanum 1, hanging 2		3
Scarlet fever	18	
Psoas abscess 1, abscess of scalp 1, alcoholism 2, asthma 1, aneurysm of aorta 2, burns and scalds 1, cirrhosis of liver 1, croup 2, cyanosis 2, drowned 1, dropsy 1, epilepsy 1, hernia 1, insanity 1, jaundice 1, obstruction of the bowels 2, rheumatism 2, arterial sclerosis 1, scrofula 1, surgical shock 1, structure of esophagus 1, sunstroke 1, syphilis 1, teething 1, gunshot wounds 2		

Jewish Maternity Extension.—By an amendment to the charter of the Jewish Maternity Association of Philadelphia, the operation of the society's work is very much enlarged, adding to its equipment a gynecological ward and operating room.

NEW YORK.

Metropolitan Hospital and Dispensary.—Dr. W. R. Dalton, of New York, has been appointed dermatologist.

The Buffalo Academy of Medicine held its quarterly meeting in the Academy Rooms, Public Library Building, September 11, 1900.

A new medical dispensary will be erected by the St. Bartholomew's Church Corporation near the present mission house of the church. The cost is estimated at \$200,000.

Examiner of Charitable Institutions.—Mary Cashen has been appointed examiner of charitable institutions by the Charities Commissioner of New York, at a salary of \$1,000 yearly.

New York Post-Graduate School.—Dr. I. N. Love will soon remove from St. Louis to New York to accept the position of professor of medicine in the Post-Graduate School of Medicine.

Steamers Held in Quarantine.—The steamers *Californian* and *Glenelg*, recent arrivals at New York from Glasgow, are held in quarantine for inspection. All on board are reported well.

Baths Blamed for Typhoid.—Two boys suffering from typhoid fever are now in Bellevue Hospital, New York, and their illness is attributed by the physicians to using the public baths contiguous to the mouths of sewers.

Toadstools for Mushrooms.—The Coroner's physician of New York recently performed an autopsy on the body of an Italian, and announced that the man died from muscarin poisoning, the result of having eaten toadstools.

Malaria in the Bronx.—Inspectors have been sent to the Bronx by the New York Health Department to investigate the complaint of citizens near Bailey and Sedgewick avenues, that open trenches there are the cause of an epidemic of malaria in that part of the city.

Ambulance Overturned.—Roosevelt Hospital ambulance was recently overturned by coming in contact with a street car. Dr. Frincke received a severe scalp wound, and the driver and a patrolman were also injured. The patient received no injuries, and was very active in helping to revive the driver.

Symptoms of Yellow Fever on the "McClelland."—The transport *McClelland*, which arrived in New York recently from Havana, is still under quarantine in the harbor. One passenger was removed to Swinburne Island for observation and treatment. If no further suspicious developments occur the transport will be released soon.

An operation for a broken back, similar in many ways to that performed about a year ago at Roosevelt Hospital on Walter Duryea for a broken neck, was performed at the Harlem Hospital on Mrs. Annie Smith. An incision was made and fragments of the dorsal vertebra removed that were pressing on the cord. The patient is improving.

At the People's Baths, Central Market Place, New York, during August, 17,124 baths were taken—an increase of 1,645 over August of 1899. Of this number, 11,767 were taken by men, 3,038 by women and 2,319 by children. On August 11 the baths were enjoyed by 1,107 persons, which was the largest number for any one day of the month.

The Spanish-American War Nurses' Association was completed recently in New York, where 60 of the nurses who served in the Spanish War have been in session for that purpose. The constitution adopted makes only those who were in actual service not less than one month during the Spanish War eligible to membership. Of these there are at least 500. Dr. Anita Newcomb McGee was elected president.

Medical Immortals in the New York Hall of Fame.—The Senate of the New York University has submitted to the judges of the Hall of Fame a list of 234 names, from which a final selection of 100 "Immortals" is to be made. The physicians and surgeons whose names are in the list are Valentine Mott, Benjamin Rush, James Marion Sims, Ephraim McDowell, and John Collins Warren.

The "Baltimore's" Sick List.—The United States cruiser *Baltimore* sent 25 men to the Naval Hospital for treatment. The vessel was held in quarantine by Health Officer Doty, of New York, for fear the men might have contracted plague while at Glasgow, but his investigation shows that there was no danger from any of the men on the *Baltimore*. The nature of the illness of these men has not been made known.

Zeta Phi at Syracuse University.—During the past year, the women of Syracuse University, College of Medicine, have organized Beta Phi, the first and only woman's medical fraternity in this country. They esteem it an honor that Dr. Elizabeth Blackwell has consented to become a charter member, she having been graduated from this college and the first woman to receive the degree of M.D. in America. The purpose of the fraternity is to bring the women of the medical profession into closer touch with one another.

The Buffalo Academy of Medicine. Section of Surgery.—At the regular meeting of this section, held September 4, 1906, Dr. VERTNER KENERSON read a paper entitled **Lymphangioma** in which he reported 2 cases, both occurring in infants said to have appeared shortly after birth; in one case the left side of the face was involved and in the other the right shoulder. In both cases operation was performed with fatal results from shock, the hemorrhage in both cases was comparatively small. In the second case elaborate preparations were made for supplying the child with normal salt-solution to prevent shock and to supply a substitute for the lymph which was lost in the previous case. The tumors were dingy blue in color, firm, not fluctuating, firmly adherent, no pulsation, no points of tenderness. The affliction in these cases is great, the children are really monstrosities, the tumors increase with age and the individuals are not able to secure ordinary employment. Microscopic examination showed that the skin and lymph spaces were involved and connected with deep lymphatics of the trunk; drawings and photographs were presented. The condition was suggested as being caused by congenital or acquired occlusion of the efferent trunk of a set of lymphatics which supply a particular part. He believes these cases to be operative if done early and with proper precautions. In discussion Dr. E. A. SMITH thought that fatality in second case might be due to a possible toxic effect of the salt-solution, as very little blood had been lost and therefore no solution required. Dr. H. MYNTER described a case of traumatic origin. Dr. C. P. SMITH also thought the salt-solution in this case toxic and described parallel cases. Dr. HERMAN MYNTER presented several cases of joint-resection.

NEW ENGLAND.

Charity.—Through the will of the late Barthold Schlesinger, of Brookline, Mass., \$7,000 have been left for charitable purposes.

Protective Societies Uphold Dr. Dunham.—At a recent meeting of the united protective societies of Springfield, Mass., the action of the medical staff of Mercy Hospital, in not allowing Dr. Dunham to treat one of his patients in that institution, was condemned, and it is said the legality of the action will be tested. Dr. Dunham is not a member of the association of physicians.

The Antiarsenic Law in Massachusetts.—The new antiarsenic law which goes into effect in Massachusetts on January 1, 1907, is arousing much criticism among the Massachusetts manufacturers, many of whom claim that the statute is nonsensical and uncalled for. The law imposes heavy penalties for the sale or possession of fabrics or paper containing more than $\frac{1}{100}$ grain of arsenic to the square yard of dress goods or $\frac{1}{10}$ grain of any other article.—[*New York Medical Journal*.]

A Physician Cleared.—Dr. Joseph P. St. Germain, of New Bedford, Mass., was recently summoned into court to answer to a charge of assault on a 5 months-old child. Dr. St. Germain is employed by the Board of Health to vaccinate. He had no recollection of this particular case, but the fact that the mother bared the arm of the infant for the operation showed that she gave her consent. Dr. St. Germain was discharged.

United States Hay Fever Association.—The twenty-seventh annual meeting of the United States Hay Fever Association has recently been held at Bethlehem, N. H., where the sufferers from this disorder are accustomed to congregate. Many new members were admitted, and a relation of experiences followed. Whether or not this is good treatment for a disease which certainly has in it a large nervous element would seem to be open to question.—[*Boston Medical and Surgical Journal*.]

CHICAGO AND WESTERN STATES.

Smallpox in California.—Two new cases of smallpox have developed at Callahans, Cal. Many of the cases are of a mild form.

Smallpox at Madison.—One case of smallpox is in the isolation hospital at Madison, Wis. The patient came from Calumet, Mich.

Physician Runs for Congress.—The Democrats of the Fourth District, St. Paul, Minn., recently nominated Dr. Alexander J. Stone for Congress.

Pension Medical Examiner Appointed.—Dr. Albert Merrell, of St. Louis, was recently appointed pension medical examiner in that city in place of Dr. R. J. Hill, deceased.

Dr. Tubbs Nominated.—The Republican Senatorial Convention of the Twenty-seventh District met in Rolla, Mo., recently, and nominated Dr. Alonzo V. Tubbs, of Osage County, for State Senator.

Succumbs to Hiccough.—For 3 weeks, John Salmon, of Assumption, Ill., suffered from an attack of hiccough, which completely baffled the skill of physicians. He finally became unconscious and died.

An Epidemic Feared.—Several cases of diphtheria are reported at Menasha, Wis., and it is feared that a number of persons have been exposed. The disease at present is confined to a Polish neighborhood.

The American Academy of Railway Surgeons began its annual convention in the State Capitol September 5 with 100 delegates from all parts of the country present. The convention continued 2 days.

The College of Medicine of the University of Illinois.—Dr. A. J. Ochsner and Dr. Alex. Hugh Ferguson have been elected professors of clinical surgery in the Medical Department of the University of Illinois, Chicago.

Missouri School of the Blind.—Dr. J. Harvey Moore, formerly of Atlanta, Ga., has been appointed surgeon to the Missouri School of the Blind. Dr. Moore also becomes a member of the Board of Managers, succeeding Dr. M. Hayward Post.

Stomach Trouble in Chicago.—Physicians are reported to have said that 75% of the population of Chicago have recently been suffering from gastritis, gastroenteritis, and cholera infantum. For the week ended September 1 there were 111 deaths from these diseases, and 108 the previous week.

Veterinarians and Regular Army.—In his address to the 37th annual convention of the American Veterinary Medical Association held at Detroit, Mich., Dr. Leonard Pearson, of Philadelphia, urged that the efforts of all the members be concentrated during the ensuing year on the securing of commissions for veterinarians in the regular army. Nearly 150 members were present. Dr. Tait Butler, of Indianapolis, was elected president.

Typhoid in Milwaukee.—Many new cases of typhoid have been reported in Milwaukee, and the source of the infection has been traced to the milk-supply. Two members of a dairyman's family are afflicted with the disease and many of his customers are suffering.

Rush Medical College.—Dr. Edwin Klebs, who has been professor of pathology in Rush Medical College, and director of the pathologic laboratory in the Post-Graduate Medical School of Chicago for several years, has resigned and returned to Germany to reside permanently.

Spiders in His Ear.—According to a lay paper the 8-years-old son of James Hawkins of Poplar Bluff, Mo., recently complained of severe, continuous headache. A local physician examined the boy, and removed 96 black spiders from his ear. This equals the famous three black crows.

Dental College Moves.—The nineteenth session of the dental department of the University of California will be held in the new building provided by the State in San Francisco. The histological, chemical, and metallurgical laboratories have also been moved to the same place, which is large and commodious.

Medicine Man Stoned to Death.—Chief Illowahe, an aged medicine man and chief of the Yakima tribe near Yakima, Wash., has been brutally stoned to death in his tent by an Indian. He had been called by the Indian to save his child, who was sick. The old man went through the usual barbaric formalities as best as he could, yet the child died.

Fire in Portland Hospital.—Recently fire broke out in the roof of the Good Samaritan Hospital, Portland, Oregon. The patients were speedily removed and laid upon the grass on the lawn, pending their removal to other places. Meanwhile the fire department had gained control of the flames and the patients who had not been taken to nearby residences were returned to their rooms.

Pennoyer Sanitarium.—Suit has been entered against the Pennoyer Sanitarium Company of Kenosha, Wis., by W. D. Perry, of Chicago, to recover \$10,000 damages on account of the death of his wife. Mrs. Perry committed suicide, and Dr. Pennoyer alleges that she did so because of ill treatment by her husband, and that there was no negligence on the part of the nurses. The suit will be bitterly contested.

Cured by Hypnotism.—George Conrad, committed to Stockton State hospital from Fresno, Cal., 11 months ago, suffering from melancholia, so far recovered after being twice hypnotized that he was allowed to accompany his mother home recently, where the hypnotic treatment will be continued. Conrad's insanity was due to the fact that playmates had made him believe that he was accused of setting fire to a barn at Fresno.

Many Charitable Bequests.—By the will of the late John Pritzlaff, of Milwaukee, Wis., the following bequests have been made: Passavant Hospital, in addition to \$1,000 heretofore presented, \$300; Milwaukee Protestant Orphan Asylum, \$300; Wisconsin Humane Society, \$100; Associated Charities, \$300; Wittenberg Orphan Asylum, now located in Wauwatosa, \$500; Orphan Asylum "Zum Kindlein Jesu" of Des Peres, Mo., \$100; Lutheran Orphan Asylum at Addison, Ill., \$200; Milwaukee Rescue Mission, \$200; and Milwaukee Protestant Home for the Aged, \$200.

Will Complete Hospital.—The hospital which the Lutheran synod started to erect at La Crosse, Wis., some time ago will be completed, the bids for the superstructure being asked for. There is in process of construction a new hospital, being erected by the La Crosse Hospital Association, and it was feared that this would change the plans of the Lutherans. They state, however, that they will not depend on the local patronage entirely, but will draw from all over the synod and from Minnesota, the Dakotas, Iowa, and Wisconsin. Their building, when completed, will cost \$60,000.

Chicago Medical College, and Mercy Hospital Appointments.—Dr. J. B. Murphy has accepted a professorship in surgery and clinical surgery in the Northwestern University Medical School (Chicago Medical College), and has

been appointed surgeon-in-chief to Mercy Hospital, with the direction of the surgical teaching in that institution. The hospital now contains 260 beds with an abundance of clinical material. A new amphitheater with a seating capacity of 300 is in process of construction. Dr. Archibald Church has been recently appointed professor of nervous and mental diseases and head of the neurological department of the same institution.

A Medicolegal Case.—The question as to whether a physician should determine the number of calls he should make when attending a patient, or should call only when and as directed by the patient, is discussed by the Supreme Court of Illinois in upholding the validity of a judgment obtained by a physician who brought an action to obtain payment of his bill for professional services. The court held that the physician was not called upon to prove the necessity of making the number of visits for which he charged. The court followed the doctrine of an earlier case in which it was said: "When a physician is called by a person to treat him or his wife, and he takes charge of the case and attends from day to day, evidently, in view of his responsibility for skilful and proper treatment, he must, in the first instance determine how often he should visit the patient, and so long as the person employing him accepts his services, and does not discharge him, or require him to come less frequently, or fix the times when he wishes him to attend, he cannot afterward be heard to say that the physician came oftener than was necessary. There was no proof that the claimant came when he was forbidden to come, or that he was discharged and continued to attend thereafter."

SOUTHERN STATES.

A Fatal Disease.—A disease is reported in Roanoke County, W. Va., that the physicians have failed to diagnose. It begins something like flux, but quickly proves fatal.

Nurses' Training-School.—The annual graduating exercises of the Nurses' Training-School of the Western Maryland Hospital, Cumberland, occurred September 6.

Fever Steamer Quarantined.—The British steamer *King Gruffydd* has been held at Baltimore until the character of the 4 cases of fever found on board can be determined.

Hospital Benefit.—A benefit for Georgetown University Hospital has recently been given. The first annual report of the Hospital shows that out of 1,397 cases treated, only 93 were pay-patients, which shows in a measure the work the institution is doing.

Arsenic in the Dinner.—Near Long's Shore, N. C., Dr. S. J. Love and family, with 5 farm-hands, were poisoned by arsenic, which is believed to have been placed in the dinner with murderous intent. Dr. Love died within 3 hours; the other victims are alive, but seriously ill.

The Charleston, S. C., Society for the Prevention of Cruelty to Animals, by the will of the late Dr. John L. Ancrum, of Asheville, N. C., will receive, upon the death of Mrs. Ancrum, \$25,000 on condition that its name be changed to "The Ancrum Society for the Prevention of Cruelty to Animals."

New Orleans Charity Hospital.—The August report of the Charity Hospital in New Orleans shows the number of indoor cases to be 1,258, with an admission list of 717. During the month 599 were discharged. The clinics give evidence of a like increase. In the male department of the surgical clinic there were 3,103 consultations and in the department of women and children 3,092. The ambulance corps responded to 148 calls.

To Dispose of Garbage.—The Baltimore Commissioner of Street Cleaning in his annual report will recommend that the city change its method of disposing of garbage. Many cities contract to have the garbage destroyed and are relieved of the expense of building a plant and the trouble of operating it. This plan will be recommended. It now costs \$15,000 annually to dispose of the refuse. It is piled on scows which must remain at their moorings for some time, during which the garbage often becomes very offensive.

Forced to Call a Physician.—Christian Scientists of Baltimore are scandalized over the action of one of their leading healers, who is just recovering from a severe illness. The young woman who has brought reproach upon the cause of Mrs. Eddy did it not only by getting sick like ordinary mortals, but by calling in a physician as other human beings do.

District of Columbia Milk Supply.—The health office has begun a fresh crusade against violations of the law regulating the milk supply of the District of Columbia. These periodical investigations and prosecutions indicate that although the laws are satisfactorily framed in the interests of the public health as far as they go, there is yet room for improvement in their requirements and restrictions.

New Y. M. C. A. Hospital.—The Railroad Young Men's Christian Association of Texarkana, Texas, has entered into a plan with all the railroad companies interested here to establish an emergency hospital in the association building. A commodious section in the place has been equipped for that purpose, and the management will be under the direct care of the local railroad physician. The hospital will be used in all cases where delays to the general hospital are experienced.

Typhoid in Baltimore.—Last week 39 cases of typhoid were reported in Baltimore, and 4 deaths resulted from the disease. During August, the unusually large number of 189 cases were reported with 37 deaths. An effort has been made by the Health Department to trace the water-supply of the sections where fever exists, but it is learned that the water from the different reservoirs intermingles before it reaches the consumer. The cases are confined to the crowded portions of the city. It is thought that the foul gases arising from the harbor, which have been augmented by the warm weather, may be responsible to a certain extent for the prevalence of the disease.

Maryland Board of Pharmacy.—The members of the State Board of Pharmacy at a recent meeting discussed the ease with which unauthorized persons may purchase deadly poisons in Maryland, and determined to have prepared a more effective pharmacy law for submission to the next Legislature. Dr. David R. Millard, secretary of the Board, said there is now no law which in any way restricts or safeguards the sale of poisons in Maryland, and a druggist may sell what he pleases. Maryland is the only State without a stringent pharmacy law. The Board decided to extend the time for registration of pharmacists to September 15. The names of all those doing business by that time and not registered will be turned over to the State's attorney.

CANADA.

A Tuberculosis-Hospital in Toronto.—The Canadian National Sanatorium Association has agreed to give \$20,000 towards the erection and equipment of a free sanatorium for the treatment of tuberculosis in Toronto, provided that the city gives an equal amount.

The Ontario Association for the Prevention of Pulmonary Tuberculosis met last week. The president, Dr. Thorburn, in his opening remarks pointed out that the association was provincial and not local in its character, and therefore deserved the approval and financial assistance which the Ontario Government has promised. He referred to the ravages of the disease and said that public and medical opinion had changed as to the possibility of practically stamping it out since the discovery of the bacillus. It was stated by the Board of Health that in Ontario alone there are 20,000 cases of tuberculosis. The inaugural meeting of the association had been held early in June, a constitution had been adopted, and a provisional board of officers elected. The draft of the constitution, submitted and formally adopted, defines objects of the association, as follows: The collection and dissemination of information as to the contagious character of tuberculosis, and as to the methods and measures necessary for public protection; the education of public opinion and the stimulation of individual and collective initiative with regard to the means of preventing the spread of tuberculosis; the enlightenment of the public as to

the necessity of the enactment and strict enforcement of sanitary laws as a method of prevention and cure of tuberculosis; the dissemination of information with respect to the danger of contagion in food-supplies, especially in the milk of tuberculous cattle, and the means of preventing the same; to encourage the erection and support of sanatoriums in suitable locations, and to such an extent as to meet the needs of the province; to encourage such cooperation of governments, municipalities, philanthropic organizations, and of individuals as shall provide sanatoriums for the people on the lines made possible by Ontario legislation.

MISCELLANY.

No Yellow Fever in the United States.—The Marine-Hospital Service has no record of any cases of yellow fever in the United States. This is a source of gratification to the Surgeon-General, and, as it is now so late, the danger of an outbreak this season is almost passed.

Obituary.—EASTON BURCHARD, at Nagasaki, Japan, September 2, aged 35.—JOHN LANGDON SULLIVAN, of Ashville, Mass., September 5, aged 73.—JOHN FRANCIS RYAN, of Roxbury, Mass., September 1, aged 29.—J. S. BRECKENRIDGE, of Stanford, N. Y., August 28, aged 60.—SAMUEL T. MCCANDLESS, of Alliance, O., August 27, aged 61.—J. G. MENNIE, of Toronto, Canada, August 24, aged 46.—JOHN A. EARLY, of Reading, Pa., September 2, aged 45.—DR. BOSOLD, surgeon of Fort St. Philip, near New Orleans, La.

A Naval Medical Board of Examiners for examination of candidates for admission to the Medical Corps of the Navy is now in session at the Naval Laboratory, Brooklyn, N. Y., and will remain in session for several months. There are now 17 vacancies in the list of assistant surgeons. Congress, at its last session, passed a law, taking assistant surgeons out of the steerage, and making them ward-room officers as soon as they entered the service, giving them the rank of junior lieutenants, and the pay of assistant surgeons in the Army. Candidates must be between the ages of 21 and 30. Circular of information can be obtained on application to the Surgeon-General of the Navy, Navy Department.

Convalescent Volunteers to be Discharged.—The Secretary of War has instructed Major General Shafter to discharge all volunteers now in San Francisco. About 400 are now there, having been sent home from Manila sick or wounded, the most of them are convalescent; all such will be discharged, the service being no longer required. This course will be followed until the volunteer regiments return for final discharge. General MacArthur has been instructed to forward all sick volunteers whom the medical officers report are able to travel or who will be benefited thereby. Those convalescents when they reach San Francisco will be discharged at once, others sent to hospital for treatment and will be discharged as soon as cured.

A Warning Against the Use of Silver-mounted Drinking Vessels.—The United States Consul at Mainz has called the attention of the State Department to the danger to the health of persons using silver-mounted glasses and porcelain wares. Certain kinds of silver-mounted glass and porcelain wares, such as cups, glasses, jars, vases, etc., have been placed upon the market. The silver on these articles, he says, is applied by means of a galvanoplastic process in baths which contain large quantities of potassium cyanid. As glazed wares have innumerable hairlike cracks, this poison enters these cracks, and the articles become a severe menace to the health of anybody using or handling them, and especially as it is impossible in the course of manufacture to remove this poisonous residuum. Only a short time ago a very severe case of poisoning resulted from the use of such ware. These goods are chiefly exported to the United States from Frankfort, Berlin, and Stuttgart.

Leprosy Colony Report.—The board of army officers detailed by General McArthur to select an island for a leprosy colony in the Philippines has completed its work and has made a report on its observations. The board was composed of Major L. M. Maus of the medical department, Captain George P. Ahern, and Captain William E. Horton. They made a tour of the islands in the southern archipelago, and

selected sites which were deemed available for the purpose. No information is forthcoming in regard to the recommendation of the board, but the impression prevails that a group of 3 small islands near the coast of Cebu has been chosen. The selection of proper territory for a population of 30,000 leper weaklings was no small matter. It was necessary to find a fertile tract adapted to the production of a variety of products easy of cultivation. These tracts must not be overpopulated, for it is no small undertaking to remove 5,000 or 10,000 people from their homes. The officers found all fertile tracts densely populated, and the land not settled was barren or very mountainous.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended September 8, 1900:

SMALLPOX—UNITED STATES.

		CASES.	DEATHS.

America's First Woman-Graduate in Medicine.

—A pleasant glimpse of the first woman to obtain a medical degree in America comes through a letter written by Margaret Dooris from Hastings, England, to the London (Ohio) *Enterprise*. She says: "We were back in Hastings in time to celebrate July 4. We invited a few especial friends. Dr. Elizabeth Blackwell was the guest of honor. She came decorated in American colors. It was through her exertions that the medical colleges of America were opened to women. She is now in her eighty-first year, but as young in appearance and in mental and physical faculties as most women of 60. She is the most remarkable woman I ever met in conversation. She is brilliantly intellectual. Everything she says is worth remembering, and yet she is not the least stilted or pedantic. Her mornings are strictly devoted to literary work; in the afternoons she receives or visits her friends, and we have had the pleasure of enjoying many interchanges of hospitality with her during our stay at Hastings.

Changes in the Medical Corps of the U. S. Army for the week ended September 8, 1900:

CRAMPTON, Major LOUIS W., surgeon, will report to the commanding general, department of Southern Luzon, for assignment to duty.

SIMS, GEORGE K., acting assistant surgeon, now at Camp McKinley, Honolulu, H. I., will proceed to Manila, P. I., for assignment to duty.

WADHAMS, S. H., acting assistant surgeon, will upon the abandonment of the post of Humacao, P. R., proceed to the post of San Juan, P. R., for duty.

BAKER, First Lieutenant DAVID, assistant surgeon, is relieved from temporary duty at the Army General Hospital, Presidio, and will report to the commanding officer, First Battalion, First Infantry, now in camp at that post, for duty with that battalion.

DEWITT, WALLACE, acting assistant surgeon, will proceed to the Presidio, where he will report to the commanding officer, First Battalion, First Infantry, now in camp at that post, for duty with that battalion.

ESCOBAR, JULIUS A., acting assistant surgeon, will be relieved from temporary duty at the Army General Hospital, Presidio, in time to enable him to report on the transport "Frederica," for temporary duty during the voyage of that vessel. Upon arrival in Manila, P. I., Surgeon Escobar will report to the commanding general, division of the Philippines, for assignment to duty.

BRADLEY, Captain A. P., assistant surgeon, is granted leave for 15 days, from about September 3.

GODFREY, ALFRED C., acting assistant surgeon, contract annulled at his own request to date August 31.

RICHARDS, First Lieutenant WM. E., is granted leave for 3 months, from about September 15.

HOLMES, THOMAS G., acting assistant surgeon, is relieved from duty at Fort Wright and will report to the commanding officer of Companies B and M, Twenty-fourth Infantry, at that post, for duty to accompany those troops to Manila, P. I.

CARTER, HENRY R., JR., acting assistant surgeon, is relieved from duty in the department of the Colombia, and will report by letter to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

WINNE, Major CHARLES K., surgeon, is relieved from duty at Fort Crook, and will proceed to Fort Porter, for duty.

DUCKER, Major ORLANDO, surgeon, is honorably discharged from the service, to take effect September 30, his service being no longer required.

BURKART, JOHN L., acting assistant surgeon, will proceed from Grand Rapids, Mich., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

CLAUSIUS, MAX F., acting assistant surgeon, will proceed from Barrington, Ill., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

LINDSAY, SAMUEL C., acting assistant surgeon, will proceed from Salineville, Ohio, to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

PATTON, IRVINE W., acting assistant surgeon, will proceed from Huntsville, Ala., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

EKWURZEL, GEORGE M., acting assistant surgeon, will proceed from Philadelphia, Pa., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

ROSS, CHARLES A., acting assistant surgeon, will proceed from Leopold, Ind., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

BAKER, CHARLES L., acting assistant surgeon, will proceed from Duffield, W. Va., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

REYNOLDS, CHARLES R., acting assistant surgeon, will proceed from Philadelphia, Pa., to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for foreign service.

STEWART, WILLIAM J. S., acting assistant surgeon, will proceed from Vineyard Haven, Mass., to Fort Slocum, and report for assignment to duty with recruits destined for the Philippine Islands.

MANSFIELD, ELMER E., acting assistant surgeon, will proceed from Wilmer, San Antonio, Tex., and report to the commanding officer, department of Texas, for assignment to duty with the Twenty-fifth Infantry, under orders for foreign service.

WOOD, Major MARSHALL W., surgeon, is granted leave for 1 month and 20 days, to take effect after the arrival of a medical officer of the Army, or an acting assistant surgeon at Jefferson Barracks, for duty.

CARTER, HENRY R., JR., acting assistant surgeon, now at Vancouver Barracks, will proceed to Seattle, Wash., and report to the depot quartermaster at that place for temporary duty.

The following named medical officers are relieved from duty at their present stations, and will report on the transport "Thomas," scheduled to leave August 1, to San Francisco, Cal., for duty on that vessel while en route, reporting to the commanding general, department of California, as indicated. First Lieutenant PERCY M. ASHBERN, assistant surgeon, and Acting Assistant

Surgeon WILLIAM J. LEH. Lyster, for instructions to return to division of the Philippines; Acting Assistant Surgeons STEVENS T. HARRIS and WILLIAM R. DAVIS, for annulment of contract.

The following named acting assistant surgeons, now at stations designated, will proceed to the Philippine Islands, via Honolulu, H. I., on the transport "Belgian King," to sail August 27: HOWARD D. LEWIS and CALVIN D. SNYDER, Presidio; LEWIS T. GRIFFITH, CHARLES A. STUTEVANT, BENJAMIN B. WARMER, JOHN D. BROOKS, JAMES I. MABEE, ROBERT C. MACY, EDWIN W. PATTERSON, VERNON J. HOOPER, JAMES J. EDMONDSON, A. BAUCE HENDERSON and WM. D. PRESTON, Army General Hospital, Presidio. Upon arrival in Manila the medical officers named will report to the commanding general, division of the Philippines, for further orders.

Changes in the Medical Corps of the U. S. Navy, for the week ended September 8, 1900:

ARMSTRONG, E. V., assistant surgeon, is granted sick leave for 1 month.
DEVALIN, C. M., passed assistant surgeon, is ordered to additional duty at the Navy Yard, Portsmouth, N. H.
GRUNWELL, A. G., assistant surgeon, is detached from the "Monocacy," and ordered to the "Brooklyn." (Orders issued by commander-in-chief of Asiatic Station.)
LIPPITT, T. M., assistant surgeon, is detached from the "Newark," and ordered to the "Monocacy."
RUSSELL, A. C., surgeon, is detached from the Naval Hospital, Yokohama, Japan, and ordered to proceed home and to wait orders.

Changes in the U. S. Marine-Hospital Service for the week ended September 6, 1900:

CARMICHAEL, D. A., surgeon, detailed as chief quarantine officer, Territory of Hawaii. August 31.
WHITE, J. H., surgeon, to proceed to New York, N. Y., for special temporary duty. September 1.
THOMAS, A. R., passed assistant surgeon, relieved from duty in London, England, and assigned to duty in the office of the U. S. consul at Glasgow, Scotland. August 31.
LAVINOR, C. H., assistant surgeon, detailed as chief quarantine officer of Puerto Rico. August 31.
ANDERSON, J. F., assistant surgeon, relieved from duty at Vienna, Austria, and assigned to duty in the office of the U. S. consul-general at London, England. September 1.
KERR, J. W., assistant surgeon, relieved from duty at Honolulu, and directed to proceed to Hong Kong, China, for duty in the office of the U. S. consul. September 1.
CORPUS, G. M., assistant surgeon, granted 5 days' extension of leave of absence. September 1.
MAQUIRE, E. S., hospital steward, upon being relieved by Hospital Steward Charles Miller, to proceed to Fort Stanton, N. Mex., and report to medical officer in command for duty and assignment to quarters. September 6.
MILLER, CHARLES, hospital steward, relieved from duty at Detroit, Mich., and directed to proceed to New York (Stapleton), and report to medical officer in command for duty and assignment to quarters. September 6.
WOODS, C. H., hospital steward, relieved from duty at Cairo, Ill., and directed to proceed to Chicago, Ill., and report to medical officer in command for duty and assignment to quarters. September 6.
LEGRANGE, J. V., on expiration of leave of absence, relieved from duty at Fort Stanton, N. M., and directed to proceed to Cairo, Ill., and report to medical officer in command for duty and assignment to quarters. September 6.
ROGERS, EDWARD, hospital steward, upon being relieved by Hospital Steward C. H. Woods, to proceed to Detroit, Mich., and report to medical officer in command for duty and assignment to quarters. September 6.
WATERS, MARK H., directed to report to medical officer in command at Chicago, Ill., for temporary duty and assignment to quarters. September 1.

Decreasing Birth-Rate in Europe.—New statistics demonstrate the fact that in all the countries of Europe, with the exception of Russia, the percentage of increase by births has been diminishing since 1891, the average decline being 3%. The greatest difference is shown by England, where births have receded from 34% to 29.1%, and the smallest by Norway, namely, 0.1%. From 1871 to 1875 the increase by birth in Germany was 39.9%, but in 1891-95 this had sunk to 36.3%, and in the year 1897 it went down to 36%. The general average from 1881 to 1885 was 36.8%, but is now 36%. More noteworthy is the decrease in Austria where in the course of 25 years it has dropped from 39.5% to 37.4. In Belgium the percentage in 1871 was still 32.1, but in 1897 only 29; and in France the shrinkage in the same period was from 25.5 to 22.4. Next to Norway the most favorable data are reported from Switzerland.—[*Medical News*]

foreign News and Notes.

GREAT BRITAIN.

Plague at Glasgow.—Another case of plague is reported in Glasgow. The report now shows 12 cases and 112 persons under observation.

Hospital at Tring.—Lady Rothschild has offered to contribute £300 towards the provision of an isolated hospital at Tring, and has promised to furnish the building throughout when it is erected. The offer has been accepted.

Crews to be Examined.—From September 10, 24 hours' notice must be given to the United States Consulate at Liverpool before vessels are allowed to sail for the United States. A special surgeon has been attached to this consulate with the object of examining the crews of outwardbound vessels.

Aberdeen University.—Miss Cruickshank has given to Aberdeen University, in memory of her brother, Dr. Alexander Cruickshank, the botanic garden at Chanoury, Old Aberdeen, extending to 6 acres, and capable of accommodating nearly 6,000 specimens. Miss Cruickshank has devoted to its endowment the sum of £15,000.

Lung diseases are increasing in the Royal navy, says Captain Rason. Since 1883 respiratory diseases in that service have increased 60% despite the abolition of masts and sails and the lessened exposure to cold and wet. Captain Rason suggests as possible causes for this increase, that the men live in hot, unlined steel ships and crowded together.

London Hospital and College.—The hospital has nearly 800 beds in constant use and no beds are closed. Being the only general hospital for East London, the practice is immense. In-patients last year, 13,234; out-patients, 189,638; accidents, 20,068; major operations, 2,568. Owing to the enormous number of patients, more appointments are open to students than at any other hospital.

London School of Tropical Medicine.—Sir W. McGregor, Governor of Lagos, will deliver the opening address at the London School of Tropical Medicine in October. Sir W. McGregor is a director of medicine of the University of Aberdeen, and his double character of physician and Colonial Governor makes him peculiarly qualified to speak with authority on the importance, from a national as well as a scientific point of view, of a special study of tropical diseases.—[*British Medical Journal*.]

A Colony of Epileptics.—The success which has attended the experiment at Chalfont St. Giles has given birth to a huge scheme for the treatment of epilepsy at Warford, near Alderley, in Cheshire. According to the *Physician and Surgeon*, a large estate formerly in the possession of Lord Knutsford has been purchased, and about £50,000 will be expended in making the necessary preparations for receiving a large number of epileptics. It is the intention to make the buildings some of the best equipped in Great Britain.

Opium Eating in England.—The existence of a considerable amount of opium eating in the United Kingdom is a fact well known, according to the *Medical Press*. The wholesale and retail chemists could throw more light upon the point than anyone else, for they are in possession of the facts of local distribution. So far as can be gathered the practice is far more prevalent in country than in urban districts. Recently a case came to light in Liverpool where an inquest was held upon the body of a clerk who died in the workhouse. A letter from the deceased gave a graphic description of the various phases of the opium habit. He stated that he had been taking 50 or 60 grains of the drug daily for 15 years. He had lately tried to commit suicide, but ineffectually, by taking half an ounce of laudanum, then one ounce, and, finally, half an ounce of opium itself. He says that during the 15 years that he took the drug he found his brain, as well as the heart, quicken in action, but that his brain had become quite "soft," he had no more thinking faculties than a boy of 10 years, and had forgotten almost all he ever knew.

CONTINENTAL EUROPE.

Prof. K. Gegenbauer, professor of anatomy at Heidelberg, has resigned his chair on account of ill health.

Medical men in Italy derive so much of their income from foreigners that most of the students now learn to speak English and German.

Journal for Theater Physicians.—In Paris a journal is published for theater physicians. Nearly every special branch of medical service now has its own particular organ.

The antiseptic qualities of fluorescent bodies are discussed by O. Raab in the *Zeitschrift für Biologie*. Microbes that may live in a solution 100 hours are killed in 6 minutes under fluorescent conditions.

French Hospital Ship in China.—The French Red Cross Society has equipped and sent to China the hospital ship *Notre Dame de Salut*. The medical staff of the ship consists of 9 surgeons, 2 apothecaries, and 12 hospital orderlies. The vessel has accommodations for 300 patients.

German Malaria Expedition.—Prof. Koch in his report (*British Medical Journal*) says that malaria at Stephansort continues to remain at a low level, although the climatic conditions have been particularly favorable to the development of the disease. The results of the experiment, which has lasted over 6 months, have been so uniform and unequivocal that they cannot be regarded as accidental. He thinks that it is directly owing to the measures adopted that malaria there has, in a comparatively short time, almost disappeared. He says further progress than has been made is not to be looked for, but the results already achieved are quite enough to prove that the hypotheses on which he entered upon these researches are correct. They indicate the principles on which a campaign against malaria is to be conducted. This does not imply that some good may not be effected in other ways and by other means. One may imagine an immunity against malaria, which under ordinary conditions is acquired only in 4 to 6 years and after repeated attacks, to be conferred artificially and in a short time. Seeing, however, that as yet we have no idea how to obtain the toxin necessary for the immunizing process, chances of progress in this direction are small. He says the prospect of exterminating the mosquitos—a radical measure were it feasible—seems remote. It is, perhaps, possible to kill the mosquitos in small districts, but to free large tracts of land of them, especially in the tropics, is beyond the means at our disposal. We could also try to protect people from being bitten, as is done to some extent by mosquito nets. None of the substances which have to be applied to the skin in the hope of keeping off mosquitos that he has tried have proved successful. Their effect is transient, and some are injurious if used for a long time. We have left, then, only the plan he has followed, which, to recapitulate briefly, is to search out all cases of malaria (the concealed ones in particular) and to render them harmless by curing them. This method of procedure is no new thing. It is precisely that which is followed successfully in cases of cholera, plague, typhus, etc.

MISCELLANY.

Queensland Food Commission.—The Government of Queensland, Australia, has engaged Dr. Maxwell, the famous sugar expert of Honolulu, for 5 years' service on the Food Commission, at a salary of \$20,000 a year.

Welsh Hospital for South Africa.—Apart from valuable gifts of hospital comforts and stores, £12,000 has been subscribed toward the Welsh hospital in South Africa. The funds in hand are sufficient to keep the hospital at the front for some time, if necessary.

For Valuable Services.—The King of Portugal has conferred the honor of "Knighthood of the Royal Military Order of our Lord Jesus Christ" on Dr. de Monbrun, consul for Portugal and Brazil in Trinidad, British West Indies, "for valuable services rendered to Portugal and to the Portuguese subjects in Trinidad."

The Russian medical service in China is said to be better than those of other European nations. The number and good organization of the Russian ambulances is especially noteworthy. At Moscow 12 new military medical corps have recently been organized and will soon start for China. Each corps consists of 4 physicians, 4 Sisters of Charity, and 82 nurses.

Yellow Fever at Senegal.—It is reported that 15% of the population of Senegal, Africa, have died of yellow fever, and that 1% are dying every day, with hopeless regularity. Experts say that there is a prospect that the present death-rate will continue. The correspondent said they were guarded by a military cordon, which fires upon those who attempt to escape. The mortality is always about 26% in proportion to the number of those attacked.

Obituary.—ROBERT LYLE MCKIRDY, of Lossiemouth, August 16.—DAVID J. MACKENZIE, of Inverness, August 17, aged 30.—JOHN TODD, of Lancaster, August 18, aged 46.—JAMES AYMER, of Bervie, August 20, aged 44.—GEORGE GIBSON, at Brierly Hill, August 20.—ROBERT GOSSET BROWN, at Walton-on-Thames, August 27.—WILLIAM EDWARD JAMES WALLIS, at the Cedars, Aldershot, August 19, aged 25.—ARTHUR WEBSTER, at Middleborough, August 18, aged 32.

Swallowing Plague Prophylactic.—Dr. Macdonald, of Adelaide, who has had a wide experience in the East, of bubonic plague, claims to have made an important discovery. He states that, if the prophylactic against the plague be swallowed, the result is as efficacious in preventing the disease as if it had been hypodermically injected, with this additional advantage, that the fever that follows injection does not ensue after swallowing the preventive. After making several experiments on animals, Dr. Macdonald and a colleague swallowed a quantity of the prophylactic, with the result that they put their blood into such a splendid condition that the plague-bacilli had no effect on them.—[*Insurance Observer*, London.]

The Plague.—During the week ended August 4, 252 deaths from plague were reported for all India. The returns for the previous week show 198 deaths from the disease. In the city of Bombay 45 deaths occurred, showing a considerable diminution upon the previous week when 81 deaths were reported. The report from Sydney, Australia, shows that on August 11, 13 cases remained for treatment, 5 were discharged during the week, and no new cases were admitted. The total number of cases to August 13 was 303; total deaths 103; total contacts isolated 1,707; total Chinese attacked 10; of these 8 died. From Hong Kong, China, 26 cases are reported for the week ended August 20, and 26 deaths from the disease.

Carcinoma of the Esophagus.—Friedenwald (*Maryland Medical Journal*, September, 1900) reports a case occurring in a woman of 31, whose family history was good and who had previously been in good health. In October she complained of difficulty of swallowing, at first solid food and later also liquids. In attempting to pass a soft tube an obstruction was encountered, 43 cm. from the teeth. Only small hard-rubber tubes could be passed, and these with difficulty. Attempts were made to dilate the stricture by means of the olivary bougie, but without avail. In December following a **gastrostomy** was performed, and at the same time the stricture dilated from below. Something was felt to give way during the forcible dilation. The patient did well for 4 days, when her temperature rose to 104° and her pulse to 140. A pyopneumothorax was discovered and aspirated. The next day a rib was resected at the angle of the scapula and a large amount of pus evacuated. The patient died without rallying from this operation. A limited necropsy permitted the removal of the diseased portion of the esophagus. The lumen was almost completely occluded. A rupture was found which had doubtless been made in the dilation from below, which had evidently permitted the escape of infectious fluid and thus set up the pyopneumothorax. A microscopic examination of the tumor showed it to be adenocarcinoma. [A.B.C.]

1.—Burdon-Sanderson delivered an address on **The cellular pathology of today** at the Thirteenth International Medical Congress, held at Paris, 1900. Some of the more striking statements are here given, although as they follow in an abstract they do not make a very connected whole. There can be no doubt but that the tendency of pathologic research has undergone a marked change since the publication of the cellular pathology by Virchow in the '50s. Formerly the histologic characters of morbid processes were the subjects of special interest. Now it is microorganisms. It would, however, be a mistake to suppose that the new science of microbiology had hindered the progress of histology. On the contrary, histologic research has never been pursued with more zeal and success than during what may be called the bacteriologic period. Reference need only be made to the discovery of karyokinesis, and to the wonderful advances made in the microscopic study of the nervous system, which we owe to Golgi and Cajal, and their followers. The cell can no longer be considered as one, but rather as a complicated machine, the working of which is, for the most part, dependent on enzymes, which, however numerous and varied may be the processes in which they are engaged, all follow and obey the universal law of adaptation, and all contribute to the protection and welfare of the organism. Today our pathologic problems relate to the constituent cells of our own bodies, the chemic functions of which present much greater difficulties to the investigator. It is not difficult to understand why more progress has been made in the investigation of isolated cells, such as the colored and the colorless blood-corpuscles, and the nucleated cells that constitute the adenoid tissues than in those relating to the constituent cells of organs. From the study of the adenoid tissues, we have learned that the nucleus not only governs the development of the cell, but that it has chemic endowments that distinguish it from the protoplasm that surrounds it. In all dystrophic conditions—*e. g.*, in the functional disorder of muscle and of liver-cell which renders these structures incapable of holding carbohydrates in reserve—in the autotoxy that manifests itself in the graver form of diabetes, in the "acid intoxication" that is associated with acute disintegration of the liver, in morbid conditions attributable to "internal secretions"; in all of these instances we have to with disorders of the chemic functions of cells. In our endeavors to ascertain the immediate and determining causes of these disorders, we may, with no less advantage at the present time than formerly, allow ourselves to be guided by the principles and methods of cellular pathology, as Virchow taught them nearly half a century

ago. The principles remain unchanged; as regards the methods, we have only to add to those we then learned the newer ones that the progress of knowledge has placed within our reach. [J.M.S.]

2.—In a former paper, Wright advanced the view that **scurvy** is a condition of acid intoxication, very similar to the acid intoxication that can be produced in the herbivora by the ingestion of a surplus of mineral acids. The condition is, apparently, more rapidly superinduced by a dietary of corned meat, meat that has been rendered hyperacid by the removal in the process of corning of the alkaline salts of the blood and the lymph, than by a dietary of fresh meat, meat that still contains these alkaline salts. Similarly, infantile scurvy would seem to be generally dependent upon the substitution of more acid foodstuffs, such as preparations of cereals sold under the designation of "infant foods" for the less acid foodstuff,—milk. Justification for the identification of scurvy with a condition of acid intoxication would appear to be afforded also by the consideration that the scorbutic condition is remedied or alleviated by the addition to the scorbutic dietary of any one of a whole series of substances which, apparently, have in common only the circumstance that they all contain an **excess of bases over mineral acids**. As estimated by a method already published, the alkalinity of the normal blood is represented by the formula N 35, or the alkalinity of the blood is such that the addition of one volume of a normal acid, 36 times diluted, to an equal volume of serum, just suffices to deprive that serum of its power of bluing sensitive litmus paper. The author reports 7 cases that tend to prove his former statements. In the first case of the series, the patient was a private soldier in the British Army. The symptoms of scurvy were present, subcutaneous ecchymosis, purpura, yellowish discoloration of the skin and edema of the right foot and ankle. The alkalinity of the blood was N 100. Doses of potassium acetate of 45 grains were prescribed for 2 days without reducing the alkalinity, but setting up diarrhea; then 30-grains doses were given, and in 2 days more the alkalinity of the blood was N 70. After 7 days further treatment the alkalinity of the blood remained the same, and 60-grains doses were ordered, and in 6 days' time the alkalinity of the blood had fallen to N 45. The patient became perfectly well. The second patient was a sergeant. The alkalinity of the blood was N 100. Four-grams doses of sodium lactate were prescribed daily, and in 5 days the alkalinity was N 35. The patient subsequently died of typhoid fever. The third patient was a soldier who had contracted scurvy during the siege of Ladysmith. The alkalinity of the blood was N 200. One gram of sodium bicarbonate was ordered 3 times a day, in 4 days sodium lactate in doses of 5 grams daily was ordered, which was later reduced to 2.5 grams daily. Two days after the commencement of the lactic acid salt the alkalinity of the blood was N 40, and the patient improved rapidly. The fourth patient was a private who had also been in Ladysmith. The alkalinity of his blood was N 150. Potassium citrate was prescribed in 2-grams doses twice daily, and in 2 days the alkalinity of the blood was N 55. Then sodium lactate was substituted, 5 grams being given in the first 24 hours and 2.5 grams in the second 24 hours, which lowered the alkalinity of the blood to N 35. The patient recovered. The fifth patient was a private soldier from Ladysmith who was suffering from dysentery and phthisis. The alkalinity of the blood was N 80. In one week, after similar treatment, the alkalinity of the blood was N 35. The patient died from pulmonary tuberculosis. The sixth patient was a soldier. The alkalinity of the blood was reduced from N 110 to N 35 in 3 days. This patient was very ill; he had, in addition to the usual manifestations of scurvy, bedsores on the buttocks, an abscess in the left cheek, delirium, and involuntary passage of feces. The seventh patient was a soldier who died shortly after he was seen. The alkalinity of the blood, obtained from the heart at autopsy, was N 100. Sodium lactate seems to be the most efficient salt for the **treatment** of the condition. [J.M.S.]

4.—Duckworth believes that **gout** as a morbid condition depends upon an inherent vice of nutrition, which is manifested by an imperfect metabolism in various organs or parts of the body, presumably in the kidneys, and probably in the liver. This trophic disorder or inadequacy leads to the formation of uric acid, probably in excess, and to the periodic retention of it in the blood. Histology throws no

light on the intimate nature of this defect, which thus relates to cellular potentiality, possibly under neurotrophic influence, and not, so far as we know, to structural alteration. The textural disability, or a tendency to it, may be primarily acquired and also transmitted as a fault, thereby inducing from time to time uricemia with gouty manifestations in the descendants. In the majority of instances, under conditions that provoke it, and in some cases independently of this, attacks of gout may grow up and come to a crisis. Such crises are attended by an alteration in the solubility of the uratic salt in the blood, whereby irritating crystals of biurate of sodium are produced and precipitated in various parts of the body. A paroxysm of gout, the sites of its occurrence, and its metastases are determined by nervous influences, probably dominated from a bulbar center, and the local attacks alight either in the joints or in the textures which have been weakened or rendered vulnerable by impaired nutrition owing to past injury or overuse. This central neurosis is an essential and transmissible feature in the **pathogeny of gout** and pertains to the arthritic diathesis generally. The uricemia of gout is peculiar and is unlike that which is induced by other morbid conditions, but the occurrence of uricemia in the gouty is by itself inadequate to induce attacks of gout. Uratic deposits in any part of the body may be removed in the course of time, but they are apt to be permanent in the least vascular tissues. These uratic deposits may occur to an enormous extent in gouty persons without the occurrence of any pain or paroxysms. The clinical features of gout indicate that both hemic changes and a neurotrophic disturbance act as pathogenic factors, and that, consequently, gout is to be regarded as a neurohumoral malady. [J.M.S.]

5.—Cobbett received a culture which resembled the *Bacillus diphtheriae* from Portsmouth which had been grown from the nasal discharge of a pony. A little girl had fallen ill with **diphtheria** and the attending physician in seeking for the source of the infection found that a pony on the premises had a purulent discharge from its nose. Subsequently the animal suffered from enlargement of the lymph nodes beneath the tongue and from laryngeal obstruction, with difficulty in breathing and retraction of the abdominal wall. Both morphologically and biologically the microorganism corresponded to *Bacillus diphtheriae*, and, although there is at present but a single observation, the author concludes that the horse is liable to nasal and laryngeal diphtheria. The fact that diphtheria-antitoxin is present in many horses suggests that diphtheria is a common disease among these animals; and this is in accord with the well-known susceptibility of some of them to the action of diphtheria-toxin. It is possible that the horse may be found to play a not inconsiderable part in the transmission of the disease. [J.M.S.]

6.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, p. 440.

7.—Hunter reports 5 cases of **peripheral neuritis** in which he studied the **microscopic appearances of the motor ganglion cells**. The first case was in the person of a man of 30, who was suffering from an alcoholic neuritis. The autopsy showed tuberculous pleuritis and peritonitis. Microscopic examination of the nerves in the feet showed a well-marked parenchymatous neuritis. The cord was examined at 19 different levels, and in the upper sacral segment scarcely one normal cell could be found, and yet in none had the changes caused a complete disintegration of the cell structure. There were examples of all the different stages of chromatolysis, from the almost normal cell to the faint and almost invisible "ghost cell." In about half the number of cells the Nissl bodies had become fragmented, giving the plasma of the cell a powdered appearance, but these fine, powdered granules still stained with considerable intensity. Yellow pigment was found in about 25% of the cells, but it was small in amount, very faint in color, and seemed to be made up of fine granules. A number of sections from various levels were stained with hematoxylin and eosin, but beyond showing an undoubted colloid degeneration in the coats of the vessels there was no abnormality. The second patient was a woman of 42, who suffered from alcoholic neuritis. The microscopic findings varied only in degree from those noted in the first case. In the third patient, a woman of 40, there was, in addition to the alcoholic neuritis, commencing interstitial nephritis. The microscopic appearances were as before described. The parenchymatous degeneration of the nerve-fibers was also found in the right pneumogastric nerve. The

fourth patient was a man of 42. There was tuberculous pleuritis, pulmonary tuberculosis, and beginning interstitial nephritis. The fifth patient suffered from chronic interstitial nephritis that followed a year after an attack of lead-palsy. In this case there were evidences of parenchymatous neuritis in the nerves of both arms. No definite chromatolytic changes were found in the cord of this patient. In studying these cases the author noted that the mesial group of cells remained unaltered throughout the entire length of the cord. This fact bears out the teaching that the cells of this group are commissural and do not send their axons into the anterior roots. In the thoracic region of the cord, where the lateral cells were fused with the mesial group, the lateral cells remained quite normal; but in the cervical and the lumbar enlargements the posterolateral subgroup presented the most marked degenerative changes. The yellow pigmentation in the ganglion cells is possibly another form, if a very chronic form, of chromatolysis. [J.M.S.]

8.—Parker was attached to **No. 6 General Military Hospital**, at Naauwpoort, South Africa, during the Boer War: While on this duty he saw **120 cases of typhoid fever**. One of the first points noted was the great difference in the virulence of the attacks according to the district in which the disease had been acquired. The cases from the Modder River, Norval's Point, Rensburg, and Arundel were the most severe. On the whole, however, no matter what the district, the later cases were less severe than those of earlier date. The most severe cases were infinitely more severe than any that the author had seen in England. Although the patients came from widely different areas and the attacks were of very varying severity, when the patients came to be treated under the same conditions the complications to which they were liable were the same. The patients were treated by the use of 5 minim doses of carbolic acid, 3 times a day. To this treatment the author ascribes the freedom from distention of the abdomen, that symptom having been seen but once; although the fact that the patients were all of considerable muscular development possibly accounted for some of the freedom from this complication. Out of 120 cases of typhoid fever there were 12 cases of hemorrhage, a fact that would tend to bear out the statement that the carbolic acid treatment has a tendency to increase the frequency of that complication. Brandy was the most useful stimulant; with a plentiful supply of this stimulant the patients seemed to be less restless and to sleep more; on the other hand, strychnin seemed to increase the restlessness. Transfusion with normal salt-solution will save a considerable number of lives; it has a wonderful effect in causing the patient to rally, and at the same time, by diluting the blood, it increases the coagulability. The author is of the impression that the individuals that submitted to the preventive inoculation had milder attacks of typhoid fever than those that did not so submit. The death-rate among the inoculated was 23% lower than that among the noninoculated; the average temperature among the inoculated was 0.9° lower for the first 10 days; but in the inoculated the temperature was 5.4 days longer, on the average, in returning to the normal. [J.M.S.]

9.—A boy, 4½ years old, with a family history of tuberculosis, was taken with symptoms of **tuberculous peritonitis** 2 weeks before admission to the hospital. The symptoms increased in severity and laparotomy was performed. The intestines were found matted together and the child's condition was so bad that the abdomen was closed without further intervention. Progressive improvement and recovery followed. In a second case, the peritoneum of the intestine of a male child of 14 months was found studded with tubercles. Union by first intention followed the operation, but nearly 3 weeks after removal of the stitches the scar broke down and caseous matter escaped. The child's condition became gradually worse and death followed about 25 days after the operation. The necropsy showed general peritonitis. [M.B.T.]

10.—Curato and Tarulli suggest that the **internal secretion of the ovaries** has the power of oxidizing compounds of phosphorus, such as those which exist in bone, so that after the removal of the ovaries there is an increased deposit of calcium and magnesium phosphate in the bones, which thus become stronger. Rössner claims to have found hypertrophy of the vessel-walls with extensive hyalin degeneration in the ovaries which had been removed in 3 cases of osteomalacia.

Phosphorus and also bone-marrow have been said to produce great improvement in several cases of the disease, and it is advisable that their action should be further studied. Croft reports the case of a woman of 35 suffering from osteomalacia to such an extent that she was unable to walk or stand alone. Double oophorectomy was performed and 4 weeks after the operation she could move about much more easily and with much less pain, although standing was still difficult. Comparing the amount of phosphoric acid contained in the urine before operation with the amount afterward, a diminution was shown of from 20 to 30 grains of phosphoric acid daily. The result in this case is in accordance with the observations of Curatulo and Tarulli, who in their experiments upon dogs found after oophorectomy the amount of phosphates in the urine was greatly and permanently diminished. Hence Croft considers oophorectomy may check the progress of osteomalacia by causing a diminution in the amount of phosphates eliminated by the kidneys. [W K]

1. A Plea for Early Naked-eye Diagnosis and Removal of the Entire Organ, with the Neighboring Area of Possible Sympathetic Infection in Cancer of the Larynx. JOHN NOLAN MCKENZIE.
2. Report of a Case of Nephrectomy for Ascending Tuberculosis, with Some Remarks on Cystoscopy and Catheterization of the Ureters in Women. HIRAM N. VINEBERG.
3. The First-aid Packet in Civil Practice, and the Organization of First-aid Societies. M. J. SHIELDS.
4. Feeding the Infants of the Poor with Unsterilized Cow's Milk. GEORGE THOMAS PALMER.
5. Severe Hemorrhage after Operations on the Throat and Nose; Report of Five Cases. ARTHUR AMES BLISS.
6. The Surgical Treatment of Laryngeal Cancer. SOLIS-COHEN.

1.—Mackenzie says that it is impossible to exaggerate the importance of **naked-eye diagnosis in the detection of laryngeal cancer**. Every resource and refinement of clinical diagnosis should be resorted to before an appeal to the microscope is made. And even when there is considerable doubt still existing after all the facts in our possession have been carefully weighed, thyrotomy should be performed, instead of removing through the mouth a piece of the suspected growth for microscopic examination. If after thyrotomy has been done the doubt still exists, as a last resort just before operating it may be advisable to remove a portion of the tumor for microscopic examination. The objections to the removal of tissue for examination are: 1. It favors autoinfection. 2. It stimulates the local growth of the cancer. 3. The method is often inconclusive. As to the treatment of malignant disease of the larynx there is only one course to be considered; total extirpation, through liberal portions of healthy tissue, of the growth, together with the neighboring area of possible infection, for early total removal of the entire organ with its tributary lymphatic glands and vessels, whether the latter are diseased or not, is the only possible safeguard against local recurrence or metastasis. In the hands of a skillful surgeon excision of the larynx and removal of the neck lymphatics is one of the simplest and easiest dissections of major surgery. Excision of only half of the larynx is permissible in very few cases. [G.B.W.]

2.—Vineberg says that **cystoscopic examinations** help in the diagnosis of tuberculosis of the kidney and in cases of ureteral fistula to determine which organ is affected. Also for diagnostic purposes **catheterism of the ureters** is useful to determine whether kidney or bladder is diseased; which kidney is involved; to ascertain the function of the supposed healthy kidney; to find a calculus in either ureter or pelvis; to find a ureteral stricture; a ureteritis; the existence of an abnormal condition, or to give light on an obscure pain in the side. Therapeutically catheterism of the ureters may be of use in certain cases of pyonephrosis caused by irrigation of the pelvis of the kidney, also to dilate strictures and remove small stones from the ureters. In closing, Vineberg reports a case in which the simple passing

of a catheter into the ureter seemed to have a curative effect, but the reason therefore could not be ascertained. [G.B.W.]

3.—Shields suggests the use of a **first aid to the injured package** for men who are exposed daily to bodily injury, such as are the miners of Pennsylvania. He also thinks it would be advisable to have certain men instructed in first-aid methods so that they may be able to help their comrades when the occasion arises. [G.B.W.]

4.—At the Trinity Diet Kitchen, for infants, in Chicago, Palmer has **fed the children of the poor** during the past summer on **unsterilized cow's milk**. The milk was obtained from one source, which was the best that could be found, and was modified at the kitchen. The bottles of modified milk were packed in large buckets of ice, in which it was carried home by the mother. The infants were seen daily and the weight of the infant, the character of the stools, the condition of the nursing bottles and the nipples were noted. In addition, the nurses attached to the kitchen called at the homes of those being fed to see that directions were followed. By this method the total mortality in 700 cases was $\frac{2}{3}$ of 1%. [This method is feasible only when the milk-supply is absolutely under the control of the physician or dispensary. When the people go into the open market to buy their milk and then modify it at home, either pasteurization or sterilization is essential to a low mortality. J.M.S.]

5.—Bliss reports 5 cases of **severe hemorrhage following operations on the throat and nose**. The first was a septum operation and the bleeding came on after the removal of the packing on the fourth day, and was only stopped by repacking, and even then oozing kept up for 2 days afterwards. The second case was a tonsilotomy in which the bleeding, though not coming from any particular point, was controlled by a large hemostatic forceps, which was left in position for an hour. The third was also a tonsilotomy, in which the hemorrhage came from a point just behind the anterior pillar, and a hemostat easily remedied matters. In the fourth case a small papilloma was removed from the lower turbinate by a cold snare, the removal being followed by bleeding so severe that it was only controlled by packing. The fifth case, and the only fatal one, was a child which had a large adenoid mass filling the postnasal space, and a markedly deformed septum. The brother of this patient was a bleeder. The child died on the fourth day after the operation, though the bleeding had been stopped for 2 days. [G.B.W.]

6.—Cohen says that in **cancer of the larynx** the only treatment is thorough removal of the organ and the connecting lymphatics. He advises, however, that a piece of the growth should be removed with a pair of punch-forceps and a microscopic examination be made before proceeding to operate. During the operation septic pneumonia is best avoided by having the patient in the semi-inverted position. [G.B.W.]

Medical Record.

September 8, 1900. [Vol. 58, No. 10.]

1. Dilation of the Cervix by Means of a Modified Champetier de Ribes Balloon. JAMES D. VOORHEES.
2. Observations on the Gastric Functions Before and After Gastro-Enterostomy. CHARLES S. FISHER.
3. A New Physical Sign in Dislocation of the Heart; Gastric Dyspnea and Pseudo-Angina. ALBERT ABRAMS.
4. Two Cases of Intestinal Obstruction following Vaginal Hysterectomy, and One after Pelvic Abscess, with a Secondary Operation in Each Case. A. GOLDSPOHN.

1.—Voorhees objects to the **Barnes bags** for the following reasons: 1. It is difficult to introduce them into a cervix admitting less than two fingers. 2. Their shape is incorrect. It is of a sort one often sees in a breech or shoulder presentation—an hourglass constriction—which does not dilate the cervix. They slip either into the uterus or vagina without accomplishing anything. 3. The material is wrong. Nature's bag is inelastic. They are very distensible. In filling them one cannot regulate the pressure. The dilation may be too forcible, consequently they burst. They soon crack and rot. 4. They are not reliable in induction of labor. 5. They are too slow a dilator in eclampsia. 6. In placenta previa they do not surely stop the hemorrhage. The author tried the

Champetier balloon, but found it not strong enough. He then had made a balloon on the same plan, but much stronger, and also less expensive. This he strongly recommends, having used it in many cases. The **advantages of the modified Champetier balloons** over others are: 1. They are easier to introduce, less bulky. 2. The shape is more like that of nature's bag. 3. They are inextensible and cannot burst. 4. They cannot get out through the cervix without dilating it. 5. They are more reliable in starting labor-pains. 6. They keep in the liquor amnii. 7. They do not rot. 8. They surely stop hemorrhage in placenta previa. 9. One can pull on the tube. 10. They are less likely to displace the presenting part. The objections to the balloons are: 1. They may rupture the membranes. 2. They may separate the placenta—only in placenta previa. But the bag either arrests the hemorrhage on being filled or when traction is made on the tube. 3. They may increase the tension in the interior of the uterus. It is not great and no harm is ever done. 4. They may displace the presenting part. This is possible, but by slow distention of the bag and by watching the presenting part during the distention, we can keep it in place. This accident occurred only once in the 72 cases. 5. The cord may prolapse. For this accident to occur, the cord must be long or about the neck. Rule: Always examine when the balloon comes through the cervix. 6. Sepsis. Balloons can be boiled. If the aseptic technic is correct there should be no infection.

Indications.—(1) To start pains, when the membranes have been long ruptured, especially in breech cases; (2) in dry labors, when the child is in bad condition—there is an umbilical souffle, or it is passing meconium, or the heart is slow or irregular; (3) in prolonged and protracted labors, oxytocics and chloral failing; (4) in rigid cervixes of all kinds; (5) in hydramnion, when it is necessary to rupture the membranes; (6) in cases of twins, when it is necessary to rupture the membranes; (7) in shoulder presentations, when a Braxton-Hicks version cannot be easily done; (8) to induce labor: (a) In cases in which a bougie fails, or when the membranes are ruptured in its introduction; (b) in albuminuria; (c) in contracted pelvis—to let the head down against the brim to engage; or preparatory to forceps or version; (d) in case of a dead fetus; (e) in chronic endocarditis; (9) in placenta previa, especially those cases in which the cervix is tough, or in which the placenta is over the os and one cannot turn easily, preparatory to version. [A.B.C.]

2.—Fisher reports 3 cases in which operation was done for **benign disease of the stomach** and in a fourth for atony, in all of which gastric analyses were made for a long period before and after. 1. Pyloric obstruction. Hyperacidity existed before, and was still present 14 months after operation. The size of the stomach was much less and the motility greatly improved, though still somewhat impaired. 2. Pyloric obstruction with hyperacidity before operation, and still present 2 years afterwards. Motility became normal and dilation reduced. 3. Remittent hyperacidity before and still present, and subject to nervous disturbances. He thinks this was a case of primary functional hyperacidity with secondary pyloric spasm and dilation. Other symptoms were relieved by the operation. 4. Dilation due to neurotic atony. There was subacidity before operation and this became much worse afterwards, and the dilation persisted, though the patient gained weight and the motility was improved. In the first 2 cases, prolonged irritation produced glandular proliferation, and as this continued, the hyperacidity was not diminished. In the third case the hyperacidity was primary and functional. Albumin digestion was nearly normal throughout the course of the first 3 cases and in the fourth it showed 42% digestion one year after operation, showing that the changes in the acid-secreting cells was not proportionate to those in the peptic cells. In the first 3 there was delayed starch digestion, while it was complete in the fourth. There was constipation in the first 3 due to spasm induced from the pylorus, and fixation of the abdominal muscles from pain, and the stools were small. In the fourth case, it was atonic and the stools were large. [H.K.P.]

3.—Abrams has frequently cured cases of **pseudoan-gina** by treatment directed to the stomach for the relief of distention which has caused dislocation of the heart. When the heart is thus dislocated upwards he says there is an area of dulness or flatness, due to compressed lung-tissue on the left side in the interscapular region, midway between the

vertebral spines and the inner border of the scapula. This may include this whole area or be as small as a silver dollar. Bronchial breathing is heard, but this and the dulness disappear when the patient bends forward, which allows the lung to expand. The only signs similar to this occur in pericardial effusions. [H.K.P.]

4.—Goldspohn reviews the literature bearing on the subject of **intestinal obstruction following vaginal hysterectomy**. He reports 3 cases operated by abdominal section for the relief of the obstruction, one of which was successful and 2 were unsuccessful. His observations are as follows. 1. According to the showing of Lenclos, ileus is more frequent after vaginal hysterectomy than after other abdominal sections. This is, as we could expect, chiefly in all cases in which the abdominal or pelvic cavity is not closed; for in these cases two or three of the chief causes of peritoneal adhesions are quite generally present, *i. e.*, (a) raw surfaces, (b) infection, and (c) a foreign body (the drain). 2. The physiologic economy of the abdomen demands that the different portions of the small intestine shall be free to migrate from place to place, therefore any opening of the abdominal or pelvic peritoneal cavity is deplorable, that engages any portion of the small intestine to assist in closing the opening or wound. This is regularly the case in vaginal hysterectomy, as ordinarily performed, and as is necessarily done in all cases of this operation in which there are extensive abraded surfaces, or in which septic features are present in the case. But in all other cases of this operation, when no intraperitoneal drain is needed, it is a just requirement that the peritoneal cavity be sealed by a closure of the wound in the peritoneum by coaptation of its edges; and that the use of hemostatic forceps or clamps, so far as it interferes with such closing of the peritoneum, should be avoided as far as possible. It is not necessary or desirable to close the opening in the vaginal vault, but it and the broad ligament should drain into the vagina. 3. The secondary operation for the relief of postoperative ileus, to be successful, must be performed early, before the mechanical obstruction has caused infection and paralysis of the bowel (peritonitis). 4. When this difficulty arises early—within 3 to 4 days after an abdominal or pelvic operation—it will often be difficult to exclude peritonitis, which also causes similar symptoms. 5. The symptoms and signs which speak mostly for ileus are: Abdominal distention without marked tenderness to touch on gentle pressure; the presence of rhythmic colicky pains; a slow pulse that is not wiry; fecal vomiting; vermicular motion of the small intestine, seen or felt through the abdominal wall; increased proportion of indican in the urine. [A.B.C.]

6. An Attack of Urticaria Occurring in the Tropics Simulating Angioneurotic Edema. JACOB S. GREEN.

1.—Herbert calls attention to certain **trophic changes in phthisis**. He says the pathologic importance of some of these changes is increased by the fact that they appear on the same side of the body as the diseased lung. The emaciation in phthisis is due mostly to the disappearance of fat and the atrophy of muscles. There is unilateral muscular atrophy of the chest, and the author appears to think the atrophy is due to reflex activity from the diseased lung. The blood takes part in the general atrophy and shows changes similar to those observed in cachexia and marasmus. The heart is usually small in consumptives. There are usually pathologic changes in the pharynx, tonsils, middle ear, and palate long before a definite diagnosis of phthisis can be made, and these complications in the great majority of cases are on the same side as the diseased lung. Mouth-breathing is a characteristic feature of phthisis, caused by chronic catarrh of the mucous membrane of the nose and by adenoids. Inequality of the pupils is often a valuable sign

of consumption, especially if of nearly constant equilateral appearance. Variation in the pigmentation of the mamilla leads to a suspicion of phthisis. The skin is always affected in this disease. It becomes rough, dry, scaly, and sallow in color. Hypersecretion of the glands of the skin is common. There is generally "atrophy of the hair" of the chest on the affected side. There may be a decided atrophy of the mamma of the affected side. Fatty degeneration of the liver occurs regularly in acute phthisis, and Pitt says that 22% of cirrhotic patients die of consumption. Among the early symptoms of this disease are gastric disturbances, and among the later ones are loss of intellectual power and increase of sexual desire. The author believes these changes are caused by a degeneration of the trophic fibers in the nerves of the parts affected, but that probably the tissue to which the nerves are distributed are primarily affected and the nerve-fibers secondarily. [A.B.C.]

2.—Roy reports 3 cases of temporary injury to the eye caused by an intense electric-light flash. In all the cases there were 2 symptoms which were always present: (1) contraction of the pupil from the retinal irritation which was so strong that it persisted for several days; and (2) pain coming on several hours after the accident. The exciting cause is supposed to be an excess of the ultraviolet rays. [G.B.W.]

3.—Osborne inclines to the belief that Graves' thyroid disease or **exophthalmic goiter** is not so rare as has been supposed, but that it is more likely to prevail in crowded centers of population, where women of the emotional, excitable, and mentally active types are more numerous. He is inclined to think that the initial cause may relate to some disorder of the uterus and ovaries aggravated by worry, overwork or emotional stress, particularly when such stress occurs at the menstrual period or during pregnancy. After a period of chronic overexcitation of the gland by these factors, some particularly violent emotion may produce such exacerbation of symptoms as to first excite the attention of patient and physician, and produce the so-called acute attack. He thinks that there is a tendency to spontaneous recovery within from 2 to 5 years, with a gradual amelioration of all symptoms. After 5 years' duration the prognosis is unfavorable. The older the individual in whom the disease develops the sooner may recovery be expected. Pregnancy after the development of symptoms often causes disappearance of the disease, possibly because this disease requires and uses up a certain amount of the hypersecretion. As to treatment, anything that tends to quiet the circulatory system without putting more blood at a greater tension in the head will do good. Strophanthus, digitalis, and like drugs should be given when there is cardiac dilation, but not otherwise. The best therapeutic agent is absolute rest in bed, mental as well as physical rest. The thymus-gland treatment of the condition has been more than usually successful. Bromids are successful to a certain point, but after that increase the debility of the patient. Theoretically, treatment with sodium phosphate should be satisfactory because of the large loss of sodium chlorid and phosphoric acid caused by the hypersecretion of the thyroid. Permanent good results should not be expected for from 1 to 2 years, and even then relapses may occur. The condition will always be temporarily better during menstruation and during pregnancy, and probably become permanently cured at the menopause. Complications should be treated concomitantly with the goiter. If diabetes occurs, perhaps codain is one of the best remedies for both conditions. All uterine disorders should be treated. [G.C.C.H.]

4.—Maduro says the safest and therefore the best general anesthetics are nitrous oxid and ether, and when given with a Bennett instrument represent the ideal form of an up-to-date anesthetic. He says his own experience with the A. C. E. and Schleich mixtures have always afforded good results and he is indisposed to believe the bad qualities attributed to them. [G.B.W.]

5.—Stoner speaks of the various theories which have been advanced to explain the phenomenon of sleep. The latest, the cerebral anemia theory, he discards with all the others. On the contrary, he believes that sleep is due to an inability on the part of the processes of the psychic neurons to be extended so as to bridge over the hiatus between them and thus carry on the functions of intellection. This occurs as the result of exhaustion of the cell of the neuron. [A.B.C.]

6.—Green describes a case of **urticaria** occurring in a man of 23, who was well developed and plethoric. The patient was in a tropical climate, was taking alcoholic stimulants, and very little exercise. His face, body, and limbs were covered with wheals, and there was some gastrointestinal disorder. A day later, the symptoms were more marked, the face, hands, and genitalia being much swollen. Purgative doses of epsom salts, a non-stimulating diet, and the external application of spirits of camphor relieved the condition after 5 days. The itching was very annoying, and always worse at night. At no time was the temperature above 100.5°. The author ascribes the condition to a meat-diet, alcohol, warm climate, and lack of exercise. [A.B.C.]

2.—Harding says in addition to the drugs used in therapeutic applications, there are many common plants that will cause **dermatitis**, idiosyncrasy, however, playing an important part. The eruption may be from a simple erythema to an inflammatory condition of the erysipelatous type. The most common plants are those of the rhus group—the poison ivy, dogwood or poison sumach, and the poison oak. Japanese lacquer may cause it even in handling pictures. Among the ordinary wildflowers are the buttercup, field daisy, goldenrod, wood anemone, clematis, and garden nasturtium. Among the drugs used in applications he has seen dermatitis being caused by tincture of arnica, balm of Gilead, hamamelis, common salt in strong solution, belladonna, and many proprietary remedies containing the essential oils. A case is given in which the "Seven Sutherland Sisters Hair Grower" caused a dermatitis. The principal ingredients of this are extract of hamamelis, hydrochloric acid, salt, and magnesia. Kerosene may cause an eruption, but he has never seen crude petroleum do so. Glycerin, almond oil, iodoform, carbolic acid, salicylic acid, quinin, sulphur, tar, and chrysarobin occasionally cause inflammation. Among substances brought into contact with the skin on account of occupation, and which may cause a dermatitis, are strong alkalies, soaps, pearline, soapine, metal and shoe polishes, paint pigments, arsenic, potassium bichromate, the various salts of mercury and even the metal, and chocolate. Animal irritants are the mosquito, flea, bedbug, black fly, wasp, bee, hornet, spider, caterpillar, and jelly-fish. [H.K.P.]

3.—Putnam advises against the sole consideration of the final outcome of **ataxia**, but urges the treatment of the treatment of the present crippling conditions in the following ways: 1. Not strength, but skill in muscular movements must be developed by massage and exercise so that the brain and lower reflex centers may be taught to respond to the feeble impulses. 2. Elementary forms of movement must be practised and not the more complex ones. 3. Combine amusement in some form in the movements, to avoid fatigue and monotony. 4. Personal instruction is necessary for understanding and obedience. 5. Two cases of tabes are cited in which many authors would consider such treatment contraindicated. One with severe pains and incoordination was taught to walk with crutches or cane and showed marked improvement. Another acute case who was unable to walk without being held up was able to walk miles in 3 months unassisted, and afterwards went back to work. [H.K.P.]

5.—Sears reports two cases of **abnormal sexual development**, one a male of 26, 5 feet 2 inches tall and of good muscular development, with luxurious growth of hair on the scalp, a little soft down on the upper lip, and devoid of a beard. The voice was high pitched, the hips broad, penis and testicles small, breasts pendulous, and nipples and areola well developed. The other was a female of 26, mentally dull, who had never menstruated, but had regular

3.—Wilcox says the tissue-changes incident to old age are (1) a pure atrophy of the constituent elements of the tissues; (2) a progressive infiltration into certain tissues of organic or mineral elements foreign to their normal condition; and (3) an exaggerated production of connective tissue. He says the changed position of the interlobar fissure in the lung of the aged, assuming a position more nearly vertical than in young and middle life, explains that a senile phenomenon may be apical in position and yet the seat of trouble be in any lobe. In searching for **senile bronchitis** it must be remembered that the costal cartilages calcify and become rigid, thus changing the symptomatology, as well as the therapeutics. Of senile pathologic conditions I claim our attention: bronchorrhea, bronchitis, pneumonia, and tuberculosis. Bronchorrhea readily runs into bronchitis in the old, and its tendency is to become chronic; and likewise, pneumonia readily supersedes bronchitis. The danger of an insidious course of tuberculosis in the aged is well known. In the treatment of senile bronchitis the expectoration must be lessened. Belladonna, apomorphin, and the nauseating expectorants fail here. **Strychnia** and **ammonium carbonate** are the favorite drugs of the author. The latter drug is given in 5 to 10 gr. doses in 2 ounces of water. It liquefies the secretions, stimulates the heart and the bronchial muscles, thus relieving venous congestion and dyspnea. The strychnia, aside from its other

therapeutic value, is a powerful stimulant to the right heart. The use of opium or any of its alkaloids is strongly condemned. Systematic massage often yields brilliant results. A warm dry atmosphere free from dust is very essential. The general care of the patient's health should be carefully looked after, a thing often neglected. [A.B.C.]

4.—Keen and Spiller report the case of a man of 47, who complained of rheumatism in the knees which had persisted for 20 years. For many years there had been some tender nodules on the palm of the left hand. At first they were painful only when compressed, but gradually the pain became continuous and very severe. Some 7 years ago 2 of these nodules were removed. One nodule in the forearm was painful occasionally. For 20 years the patient had suffered from fistula in ano, for which 2 ineffectual operations had been done. Keen operated, removing the small tumors from the palm of the hand and forearm. They were shelled out without difficulty, and all were **neurofibromas in the substance of the ulnar nerve**, or its branches. The fistula was likewise operated upon and the patient made a good recovery. Keen says that operation is essential for the removal of these tumors, for they steadily increase in size, and there is increasing pain and impaired usefulness of the member. Malignant degeneration in a nerve after neurofibromas have been removed is by no means unknown, but the risk incurred by such an operation is justifiable in view of the symptoms produced by the tumors, and that malignant degeneration may occur in tumors of this kind which are not removed. If they exist on the side of the nerve they should be carefully dissected away, removing as far as possible all the diseased tissue. If the tumor is too large or too intimately connected with the nerve to be thus removed, a resection of the entire nerve, or amputation of the limb may become necessary. Spiller gives an exhaustive report of the microscopical findings in these tumors. It is too long and technical for abstract. [A.B.C.]

5.—Davis reports 2 cases of **ruptured ectopic pregnancy** wherein the symptoms differed materially from those accepted as classic under such conditions. The first was a primigravida of frail physique and highly organized nervous system, who had been 10 years married. She had menstruated regularly and had never been pregnant. She supposed herself to be in perfect health. During a ride of 2 miles on a bicycle at a rapid rate she was seized with a sharp pain in the right lower quadrant of the abdomen. Soon there was manifest shock, which was the only abnormal condition. She soon recovered from the shock. A vaginal examination revealed nothing. It appeared that she had gone 1 or 2 weeks beyond the expected menstruation. There was no tumor, no enlargement of the womb, nor any other evidences of ruptured ectopic pregnancy. A few hours after recovering from the shock, she again grew worse and on opening the abdomen there was found an ectopic gestation in the right tube. The wall of the tube had ruptured and the orifice had been temporarily closed by a clot. Later this had given way and caused the second hemorrhage. A careful operation was done, but the patient perished from shock. The second case was a woman of 40. Her only child was 19 and she had menstruated regularly. For several months there had been pain in the stomach and nausea. Her menstruation had been absent for nearly 2 months. Eight days before coming under observation she had pain in the abdomen. She denied the possibility of pregnancy. She was suddenly seized with sharp abdominal pains and severe shock. On vaginal examination the womb was not enlarged, was freely movable, and there was no tumor, exudate, nor mass in the pelvis. The cervix was unaltered. The author believed, even in the absence of classic symptoms, that the patient was suffering from ruptured ectopic pregnancy. Laparotomy was performed and an early embryo was found just above the right cornu of the uterus. It with a mass of bloodclot was immediately removed. The patient made a good recovery. The author reports a third case in which all the classic symptoms of ruptured ectopic pregnancy were present except shock. A sign of ectopic gestation so often present—a tumor in the pelvis—was absent. By careful investigation and inquiry it was believed that intestinal colic had given rise to the symptoms. The subsequent history of the case proved this to be correct. [A.B.C.]

6.—Francine reports **tabes dorsalis occurring in both husband and wife, negroes**. The author says he

knows of no previous case in which this disease occurred in both husband and wife in the negro race, though Raecke has collected 22 cases of tabes occurring in both husband and wife in which the subjects were white. The man, in this case, aged 48, was very dark and denies the possibility of any white blood in his family. He has been rheumatic since 10 years of age. He is now suffering from phthisis. He had a hard chancre at 17, for which he received specific treatment, and did not suffer a secondary eruption. There has been complete loss of sexual power for 2 or 3 years and he has been married 12 years without children. About 5 years ago the patient began to suffer from difficult vision; he has lightning pains in the legs and body, is ataxic, has girdle sensation and numbness in the soles of the feet. He has bladder trouble, shortness of breath, kneejerks absent, and there is marked dissociation between superficial and deep sensation. Babinski reflex is absent. The wife of the above patient is 52, very dark, and denies any white blood in her family. She has enjoyed good health, except that for the past 10 years she has been nervous. By a former marriage she had 2 children, one of which was still-born at term. She has not been pregnant by her present husband. She has used a sewing machine constantly for the past 35 years, which the author thinks may have some etiologic relation to the disease. About 2 years ago she began to suffer from sharp pains in the legs and body, following which her gait was ataxic. She has the girdle sensation, dimness of vision, ptosis of the right eye, and flattening of the right side of the face. There is a partial double ptosis of the external oculars. There are 2 anesthetic patches on each breast. Kneejerks, plantar reflexes, and Babinski reflex are absent.

7.—Clemow in concluding his article on the **clinical aspect of plague** discusses its effect on other parts of the body. On the **circulatory system** the most noticeable effects of plague are an increase in the pulse-rate, relaxation of the bloodvessels, diminished arterial tension, diastolic of the pulse and exhaustion of the heart-muscle. The latter may be the cause of heart-failure and death. Hemorrhages in various parts of the body frequently occur in plague and give rise to appearances of great diagnostic value, especially postmortem. The presence of these hemorrhages postmortem are next to buboes in diagnostic value. External hemorrhages are rare. Deep hemorrhages around buboes are common. These probably have to do with the presence of the glistening gelatinous infiltration around the buboes. Hemorrhages on serous and mucous membranes are commonly seen in plague-cadavers. Hemorrhages into solid organs are commonly found and are small and punctate in character. The **respiratory system** is characterized by the presence of catarrhal or inflammatory involvement of the air-passages, by ronchi of various characters and not infrequently by loud moist rales. The respirations are more frequent, and if the disease lasts for 3 or 4 days there is hypostatic congestion. Hemoptysis is rare. Among 502 cases of plague, 17 developed secondary pneumonia and 12 developed primary plague pneumonia; those having the latter developed no buboes. Necropsy showed the lungs to contain pneumonic patches of varying size and closely resembling embolic infarcts. The pneumonic form of plague is in most epidemics the most fatal, and generally regarded as the most infectious. The **genitourinary system** is characterized by diminished urinary secretion, by albuminuria, in most cases, and in a few cases tube-casts, indicating nephritis. The presence of blood in the urine is rare. Retention of urine is common, due to the influence of the disease on the nervous system. The **hemopoietic system**: the spleen is occasionally slightly enlarged, but this is not of diagnostic value, in fact the enlargement can be detected during life in but few cases. The enlargement of one or more lymphatic glands, constituting a bubo, is the most valuable diagnostic sign of plague. It is absent in the primary pneumonic form of the disease, but present in over 90% of all other cases. The gland or glands become swollen and tender, but there is no other constant character about them. The tenderness is characteristic. Buboes, as a rule, appear within the first two or three days. Deep sloughs involving the whole bubo and skin over it are apt to occur. Among 446 patients 60% had the primary bubo in the groin, and 80% of these cases proved fatal; 18.3% had the primary bubo in the axilla and 82.7% of these were fatal; and 9.4%

had the primary bubo in the cervical region, and of these 84.1% were fatal; while among patients with multiple buboes the mortality was 79.2%. Other local lesions of plague are (1) collections of pus sometimes giving rise to furunculosis; (2) patches of necrosed skin; and (3) blebs of watery fluid. The author says the remarkable differences between the clinical picture which may be presented by two given patients suffering from plague, or by the same patient on two successive days, find their exact analog in the marked differences in the rapidity of spread, mortality, proportion of persons attacked, relation to climate, soil, altitude, and other concomitant conditions. He says there appears to be little doubt that the toxins of plague are primarily nerve-poisons, and that the affections of other tissues and organs are to a very great extent due to the profound disturbance of the nervous mechanism which controls their action or nutrition, or both. [A.B.C.]

8.—Frazier reviews the literature which has been published within the last year, bearing upon **surgery of the stomach**. That especially noteworthy concerns the establishment of a communication between the stomach and the intestines. Gastroenterostomy has superseded pyloroplasty, pylorotomy, etc. The posterior operation has the choice. Murphy's button is still a favorite. Murray prefers to introduce this button through a linear incision closed with uninterrupted sutures rather than by the purse-string suture. This prevents puckering of the walls of the stomach which may interfere with union at some point. Malignant pyloric stenosis remains the chief indication for gastroenterostomy. Of 38 cases collected up to 1892, in 21 the cause of the stenosis was carcinoma; the remaining causes were benign stenosis, congenital stenosis, gastritis, hour-glass contraction, gastropotosis, and motor insufficiency. Observations have been made upon the effect of regurgitation of the bile, which occurs in not a few cases. It appears that this regurgitation has no disturbing influence upon digestion. Masse established a fistulous communication between the common bile-duct and the stomach to determine the effect of bile upon digestion; no evil effects were observed. There has been much literature treating on the subject of surgical interference in gastric ulcer; the subject is still *sub judice*. In cases of acute perforation, the necessity for immediate operation admits of no dispute. According to Lund, the percentage of recoveries during the period 1897 and 1899, in cases operated upon during the first 12 hours, was 86%, and within the first 24 hours was 73%. It appears that 52% of ulcers are on the anterior wall, 31% near the lesser curvature, 27% near the cardiac end, 13% near the pyloric end, and 8% upon the posterior wall. Hemorrhages into the stomach furnish another indication for operation, both repeated copious hemorrhages, and frequent small hemorrhages associated with anemia and stomach dilations. The mortality, according to some observers, varies from 60% to 70%. Operation on the stomach for malignant stenosis at the cardia should be done at once after diagnosis is made without regard to the degree of dysphagia. There have been up to the present time 9 cases of total gastrectomy. Of these, 4 are still living; 2 died, 14 and 7 months after the operation, respectively, and the remaining 3 died upon the table, or within 36 hours. The mortality of this series is 33%. Robson has collected 14 cases of partial gastrectomy, in which at least three-fourths of the stomach had been removed for cancer. In this series, the mortality was 28.5%. [A.B.C.]

1.—Clemens believes that **Pfeiffer's bacillus** is the cause of influenza. In many cases, however, it is doubt-

ful where the bacillus is located. The accessory sinuses of the nose and the nasopharynx should be thought of, as suggested by Bäumler. Clemens found the bacillus in 12.6% of the cases he examined. He shows by curves the **seasonal incidence** of the disease, the majority of cases falling between the end of November and the end of April. [D.R.]

2.—A slight, yellowish discoloration is not rare in grave heart disease. Some have thought it due to bile pigment, and some have ascribed it to other pigments. Ott examined 12 cases, using in addition to the Gmelin test, Salkowski's modification of Huppert's test (precipitation with calcium chlorid). He obtained **positive results** in 12 cases. He was also able to determine that in catarrhal jaundice the elimination of bile pigment outlasts the elimination of urobilin. [D.R.]

3.—Klein reports a case of **heat-stroke** cured by venesection. [D.R.]

4.—A case of **uremic convulsions** followed by coma cured by bleeding. The author also refers to a case of pneumonia in which he believes a timely venesection saved life. [D.R.]

5.—Batsch has treated **intestinal obstruction** with heroic doses of **atropin**, injecting as much as 5 mgm. ($\frac{1}{15}$ gr.) twice in one day. In 2 cases in which stercoraceous vomiting had already set in the atropin seemed to bring about a cure; in a third case the atropin failed and an operation had to be done. It was found that the intestinal obstruction was due to a parametric band. The atropin, however, seemed to prevent gangrene and to facilitate the return of the intestines to the abdominal cavity. Whenever atropin is used careful observation of the patient is always necessary. [D.R.]

6.—Mock reports a case of a **foreign body**, consisting of a splinter of steel, about the size of a pfennig, lodging **within the eyeball**. The symptoms and history of the injury led to the suspicion of its presence and by means of the x-rays it was seen that the foreign body was situated in the dangerous ciliary region. As conservative treatment had failed to reduce the inflammation previous to the localization of the particle with the x-rays, immediate operation was decided upon. Under deep narcosis a broad flap was raised from the conjunctiva, and after one futile effort the particle of steel was successfully removed by the use of Hirschberg's magnet. The wound healed rapidly and the patient recovered a useful eye. The prognosis, however, was not so favorable, because hemorrhages or loosening of the retina could at any time more or less destroy the function of the eye. [G.B.W.]

7.—Walz describes a **simple incubator** for the physician's use. [D.R.]

8.—In this third part of their article on **hand disinfection**, Paul and Sarwey discuss the possibility of varying results which may follow the researches of different observers because of the different methods of removing the germs from the hands to the culture-media. Other sources of error may be due to: (1) Peculiarities of the skin of different hands; (2) the removal of the bacteria from different portions of the hands; (3) the failure to make quantitative tests; (4) the failure to have proper culture-media kept at a proper temperature; and (5) difference in the length of time of observation. But none of these is of as much importance as the employment of different methods of removing the germs. By using a small splinter of wood many more bacteria can be removed than by either a silk thread or immersing the finger directly into the culture-media. Also the method of using a small bit of wood possesses so many practical advantages of manipulation that it is much the best of the three. [G.B.W.]

Berliner klinische Wochenschrift.

July 23, 1900. [37. Jahrg., No. 30.]

1. Our Knowledge of the Anemias and Their Treatment. SENATOR.
2. Concerning Migraine with Coincident Eye-Muscle Paralysis. W. SEIFFER.
3. The Concerted Fight Against Phthisis in Germany. PANNWITZ.
4. The Etiology and Therapy of Tabes Dorsalis. P. K. PEL.
5. The Pathology of Morbid Tumors. O. ISRAEL.

1.—Senator discusses **chlorosis, pernicious anemia, and mountain anemia**. Only the last is really an essential anemia; the other 2 have some extrahemic cause, which has yet to be discovered. In some cases of grave anemia there is a latent carcinoma of the stomach or malignant growth of the bone-marrow. In the latter the presence of albumosuria may aid in the diagnosis. Regarding the **treatment of chlorosis**, he advises that attention be first paid to the gastric catarrh which is often present. For this he gives either hydrochloric acid or mineral waters—either the alkaline or the alkaline muriatic waters, such as Emser, Gleichenberg, etc. Later the saline chalybeate waters are indicated, viz.: Elster, Franzensbad, Homburger, etc. An artificial chalybeate water may be made with pyrophosphate of iron. Of pharmaceutical preparations, Senator prefers the ethereal tincture of chlorid of iron and ferrated ammonium chlorid. Arsenic and quinin are sometimes useful. Among newer procedures, the **sweat-cure** by means of different forms of baths has given very satisfactory results. Venesection is not indispensable and may do harm. In the diagnosis of pernicious anemia Senator lays stress upon the presence of **motile megalocytes**. His treatment of the disease presents nothing new. **Mountain sickness** (anemia montana) is an **anoxemia**, a condition due to diminution of the amount of oxygen in the blood. It manifests itself by palpitation, oppression, vomiting, fainting, bleeding from the nose and mouth, etc. The only sensible treatment is the return of the patient to a lower altitude. [D.R.]

2.—A case of **migraine** in a man of 49, that had begun at the age of 8 and had been associated with coincident attacks of **oculomotor paralysis**. Eventually the latter became permanent, and the man had ptosis, external squint, and dilated pupil. The cause of such a condition is probably a disturbance of the circulation in the region of the nuclei or roots of the oculomotor nerve. At first the disturbance is only transient, but afterwards it becomes permanent. [D.R.]

3.—An interesting article detailing the magnificent results accomplished in Germany since 1895 in the development of the **institutional treatment of tuberculosis**. The great advantage which Germany has in this respect is the national insurance law, which insures from 14 to 15 millions of the 53 million inhabitants of Germany against invalidism in consequence of internal disease. As these 14 to 15 millions insured represent, with their families, a population of 34 or 35 millions, this vast number of people come under the beneficial effects of the law. The law even enables the insurance associations to treat persons who are threatened with disability. The paragraph in question has been applied particularly to tuberculosis, so that the insurance companies have established sanatoriums where persons are treated even before they have become incapacitated. At present facilities exist for treating 20,000 poor persons for 3 months each in sanatoriums and other institutions. The results have been excellent, and the cures have varied from 71% to 82%. Another beneficent institution is the **dispensary for tuberculosis**. The first one was established at the Charité in Berlin, and is not merely a dispensary, but is also a place for careful study of the patients and for special treatment and advice. The insurance law provides that when the insured person is sent to an institution for treatment, his family shall receive one-half of the sum expended for the patient's support. As this stipend is small, about 10 marks (\$2 50) per week, a movement is on foot to have the law so changed by the Bundesrath that the insurance companies may be able to pay to the family more than half of the sum expended for the treatment of the wage-earner. Societies have also been formed, especially among the women of Germany, to secure change of occupation for persons who have been treated in sanatoriums. One society in this way succeeded in obtaining more hygienic employment for 41 out of 53 cases treated in the institution at Grabowsee. [D.R.]

4.—Pel believes in the **syphilitic origin** of the majority of the cases of **tabes**, but how the syphilis acts he is, like all others, unable to explain. It is remarkable that tabes seems to follow particularly the milder forms of syphilis. Syphilis is not the only cause of tabes, however; there are other factors, at least, in a small percentage of cases. The best prophylactic against tabes is not to become syphilitic, and when infection has taken place to receive proper treatment. When the

disease has once developed not much can be done. Only in rare cases is mercury indicated. When optic atrophy exists it should not be employed. Suggestion accomplishes considerable. Strychnin injected hypodermically may be of value in weakness of the bladder, etc. There is no specific, although silver nitrate and its succedanea may have some beneficial effect. For the pains of tabes, in addition to the coal-tar products and chloral, the local use of ichthyol may prove of value. Flannel binders, cold or warm compresses, may also be useful. The suspension treatment and the postural stretching of the spinal cord are viewed with disfavor by the author. The Brown-Séquard treatment is of no value. Arsenic seems to counteract the general debility. For the treatment of the ataxia the **mechanotherapy** of Frankel is recommended, although its application is not described. Everything should be done to keep up the patient's spirits. As the author says, "We should not forget the man in the treatment of the tabes." [D.R.]

Wiener klinische Wochenschrift.

July 5, 1900. [13. Jahrg., No. 27.]

1. The Thermal Springs of Gastein. LUDWIG and PANZER.
2. Basedow's Disease with Symptoms of Myxedema. JOSEF A. KIRSCH.
3. Colic Pain. ROBERT LUCKE.

1.—A careful analysis of the famous thermal springs of **Gastein** in the Salzburg. [D.R.]

2.—A woman of 33 had typhoid fever in January, 1899, and never fully regained her strength. In August of the same year she fell down the stairway and was badly frightened. Symptoms of **exophthalmic goiter** immediately developed. Within 2 months, however, the palpitation lessened and **myxedematous swelling** of the face and of the lower extremities occurred. In addition, there was a noticeable forgetfulness. The goiter became fibrous, the uterus passed into a stage of atrophy, and the skin was dry. [D.R.]

3.—Lucke believes that colicky pains are produced under all circumstances by **distention of a hollow viscus**, and that the passage of calculi in itself is not the cause of colic. In the case of the intestines the internal pressure is increased, not alone by an augmentation of the quantity of fluid and gas, but also by contraction of the circular muscles above the obstruction. [D.R.]

Neurologisches Centralblatt.

1. The Electric Reactions of Degeneration of the Levator Palpebrae Superioris with Remarks upon an Isolated Traumatic Paralysis of the Oculomotor and of the Trochlear Nerve. BREGMAN.
2. Speech Disturbance and Speech Development. LIEBMAN.
3. The Occurrence of Cerebral Palsies After Influenza. GUTTMANN.

1.—Bregman calls attention to the fact that with the exception of 2 cases reported by Wertheim-Salomonson, no one has been able to produce **motor manifestations by the electrical stimulation** of the muscles of the eye. He then reports a case occurring in a man of 55 who, 4 weeks previously, had a severe fall producing an injury over the left eye. This was followed by severe headache, ptosis, moderate dilation of the pupil, and loss of reaction to light. There was also paralysis of the muscles supplied by the oculomotor and trochlear nerves. If a small electrode were placed directly beneath the orbital region and a galvanic current then passed through, a distinct slow elevation of the eyelid occurred. This was evidently due to the increased susceptibility of the muscle and to galvanic stimulation. Faradic stimulation failed to produce any contraction. In another case of congenital ptosis, the reaction did not occur, but was found in a third case in which the symptoms had followed a severe injury to the right temporal region. The fact that the reaction can be obtained in the levator palpebrae and not in other muscles of the orbit is explained by fact that the fibers of the former are placed further forward and can be reached more readily by the current. The lesion

in the case was probably situated either at the point where two nerves pierce the dura or where they pass through the superior orbital fissure. The Argyll Robertson pupil he regards as an evidence of gradual restoration in the function of the nerve. [J.S.]

2.—Liebmann accepts Kussmaul's division of the period of the **acquisition of speech** into 3 stages. The first commencing about the end of the third month consists of inarticulate sounds without significance. The second extends over a longer period and consists in the production of the actual sounds used in speech, not, of course, collected in the form of words. Usually it begins early in the second year and extends to the end of this period, when the child commences to say words that have to it and its auditors a definite significance. Among the conditions that can cause disturbance in the normal development is deafness occurring at birth or developing during the first year. Patients partially deaf may under certain favorable conditions learn to speak, but do not acquire modulation of the voice and have great difficulty in distinguishing between certain vowels and consonants. In case deafness develops just before complete speech is acquired, the child usually becomes dumb. Any disturbance of the organs of expression of speech, such as cleft palate, may, by rendering the production of certain essential sounds impossible, prevent the child from acquiring speech perfectly. Ognathism, either of the upper or lower jaw interferes with the pronunciation of the "s" sound and is spoken of as sigmatismus simplex. Lispering also interferes with speech-development. If these anatomic defects are not removed until later, normal speech may never develop. Lesions of the higher nerve-centers that interfere with speech, as those productive of stammering due apparently to awkwardness in the speech organs and those in which this awkwardness is so extreme that the child remains dumb. Finally there is a condition called agrammatism in which the child never acquires the faculty of forming correct sentences. Of this there are 3 groups; in the first the child cannot form normal sentences, and even fails to use any inflections correctly by repetition. In the second it also fails to speak grammatically, but can repeat short sentences correctly. In the third class it uses sentences and occasionally inflections, but the formation of the sentence is defective. Repetition is usually perfect. These patients usually are deficient in intelligence, but some of them simply represent an imperfect development of the speech-functions. [J.S.]

3.—Guttman reports two cases characterized by the development of **motor disturbances after influenza**. The first, a boy 17½ years old, noticed 4 weeks after the attack that the right leg was weak and the right arm could not be used as readily as before. This condition continued to increase and began to be associated with occasional headache, dizziness, and an irregular, almost drunken gait. Examination of the eyes showed that there was convergent strabismus, and almost complete paralysis of the right eye. The right facial nerve was paralyzed in all 3 branches. There was a tremor of both hands, particularly on intended movement, no disturbance of sensation, but increase in the patellar reflex and ankle-clonus of the right side. Intelligence was normal. The lesion was probably in the cerebellum or in the medulla oblongata. The second patient, a woman of 54, had had a slight attack of influenza, after which she noticed increasing weakness in the right arm and leg, then had severe and repeated vomiting and headache. The paralysis was found to include the right side of the face and eye. The author believes these cases prove the very deleterious influence influenza may have upon the central nervous system. [J.S.]

13.—Czerny in speaking of the **treatment of cases of inoperable cancer** says that the use of morphia should be put off until one sees that the end is approaching, less powerful remedies being used to control the pain of the earlier stages. When ulceration is present much relief can be obtained, at least for some months, by thorough curetting and cauterization, preferably with chlorid of zinc. Though the relief obtained by this procedure is generally rather transient, cases have been reported, some with undoubted correctness, in which a permanent cure has been effected. For the general treatment of inoperable cases of malignant disease a properly established hospital affords much better conditions than the ordinary home, and Czerny believes thoroughly in the construction and maintenance of such cancer sanatoriums. [G.B.W.]

14.—Krönlein has gone carefully over the literature treating of **operations for the relief of rectal carcinoma** and compiled a number of tables of the results of the leading surgeons of Germany. His views, as formed after a careful study of these statistics, he sums up in the following sentences: 1. Extirpation is the sovereign method of treating cancer of the rectum. 2. About four-fifths of the cases of extirpation of the rectum for carcinoma recover from the operation and the wounds heal. A permanent cure is obtained in at least one-seventh of the cases. 4. The functional results are the best when it has been possible to remove the diseased portion of the rectum and still leave intact the sphincter and anus. 5. The total removal of the whole of the rectum greatly interferes with the functional result but renders the proportion of cures greater. 6. The method of excision, whether perineal or dorsal, depends on the character of the case, and one may be used to complete the other. 7. The sacral method is especially appropriate for the cases in which the growth is situated or extends high up on the gut. 8. In operations for the removal of cancer of the rectum, it is to be remembered that the rules of plastic surgery apply here with the greatest of force, hence the proper placing of sutures and the adaptation of flaps of mucous membrane. [G.B.W.]

16.—Tauber reports a most interesting case of **cerebral hernia** in a woman of 30. She had a small tumor in the right orbit at the time of her birth, but could see with both eyes during the whole of her childhood. At the time of examination there was a large mass occupying the whole of the temporal region and spreading forwards so that the upper lid was several times its normal size. When the lid was lifted the eyeball was seen to be greatly shrunken, tests showed it to be perfectly blind, and the conjunctiva was red and fleshy in appearance. The bony structures were markedly diminished in size on the right side as determined by palpation through the orbit and mouth. The diagnosis was very uncertain, the possibilities including some form of angioma, atheroma, cysticercus, carcinoma of the lachrymal sac, or some kind of intracranial growth. At the operation, undertaken to remove the hypertrophied lid, it was discovered that the dura mater projected into the deep part of the orbit, and on incising it a quantity of yellowish fluid escaped and the brain-substance could be seen pulsating at the bottom of the wound. After a good deal of difficulty the cut in the dura was closed and the wound packed with iodoform gauze. The patient died on the sixth day after the operation. Necropsy showed that the case was one of congenital cephalocele basilaris complicated by external hydrocephalus, which pushed the dura through a congenital defect in the base of the skull into the orbit, producing a meningeal hernia. The increase of the fluid within the skull caused

more and more a gradual separation and thinning of the bones concerned. [G.B.W.]

17.—Strube in speaking of **glanders** as a disease of man says that it is always the result of an inoculation of the specific bacillus either from an animal or from another man. The infection may take place either through an abrasion in the skin or may gain access to the blood through the mucous membranes, preferably near their junctions with the skin. The germs may also be inspired, setting up pulmonary glanders. Pathologically, the disease is to be divided into two groups; one in which the process remains localized at the point of infection either in the nose or on the skin, and another in which a pyemic condition is produced with the formation of secondary foci; in other words, there is a local and general manifestation of the disease. The local disease is characterized by the formation of nodes and infiltrations which tend to break down and suppurate. Clinically we see nodes, infiltrations, pustules, abscesses, ulcers, phlegmonous inflammations, etc. The disease may be acute or chronic, and may heal spontaneously or may proceed in its devastations until death occurs. Sometimes at the point of inoculation there will be very little reaction even in the severest cases and then it is often most difficult to differentiate this disease from typhoid. The germs spread through the blood. The diagnosis can always be made by inoculating a guinea pig or other animal with the germs taken from the nose or cutaneous lesion. Mallein may be tried, but it is not absolutely reliable. The treatment of the disease must be carried out on the principles of antisepsis that would govern another severe infection; abscesses are to be opened, ulcers scraped, and nodes excised. [G.B.W.]

18.—Körte says that the most insidious tumors, the small ring-like, stenosing carcinomas, which so easily lead to constriction of the intestine, are most difficult to palpate through the abdominal wall, and the more stenosis there is the more difficult is their recognition. A very important help in the diagnosis of these tumors is the characteristic obstructive symptoms which they present. When a patient in middle age becomes gradually more and more constipated with attacks of colic and pain and with the borborygmi of intestinal obstruction which do not yield to proper medication, a diagnosis of stenosis would almost certainly be correct. But after a diagnosis of stenosis has been made out one must differentiate between the various forms of obstruction, though in the majority of cases a carcinoma will be found. The aim of the treatment must be a radical removal of the diseased area of intestine by resection, and when this is not advisable because of advanced state of the disease, entero-anastomosis and colostomy are suggested. In 19 cases of malignant tumor of the large intestine treated by resection 12 recovered and 7 died. Of the 12 cases, 5 remained free from return of the disease for a period of from 3 to 8½ years. Generally speaking, resection for intestinal stenosis should be undertaken only when the stenosing tumor can easily be drawn forward so that one, by proper use of gauze-packing, can operate extraperitoneally, and when the condition of the patient will permit a long operation. In conclusion Körte reports 62 cases of malignant tumors of the large intestine on which he has operated. [G.B.W.]

20.—See PHILADELPHIA MEDICAL JOURNAL, Vol. VI, p. 152.

21.—Zabludowski does not class the disease of **piano players** among the occupation neuroses, but says it is a neuritis of one of the nerves of the arm, having its origin in a muscle or joint which has been injured by too much playing. The majority of the persons who suffer from this disease are pupils in a conservatory, who have small and thin bones or weak joints, and hands altogether too small to properly span the ordinary key board. There should be a piano of smaller size for children, so that their smaller hands will not be unduly overtaxed. The treatment in these cases should consist in rest and not in hard massage and various exercises. [G.B.W.]

23.—Reisinger reports an interesting case of hydro-nephrosis in a man of 27. He gave a history of frequent attacks of pain, many of the attacks being followed by a copious flow of urine, but the urine was always free from pathologic constituents. An exploratory operation showed that the kidney was displaced downwards until its lower pole was only 3 cm. above the bladder. As it seemed impossible to remove the displaced organ because of its intimate adhe-

sions to the surrounding structures it was decided to perform a **nephrocystanastomosis**. A temporary urinary fistula was first established, opening between the symphysis and the umbilicus. Fourteen days later an anastomosis between the greatly dilated kidney and the bladder was made and a catheter placed through the bladder into the hydronephritic kidney and left in situ. The catheter was removed on the fourth day on account of irritation caused by its presence. At a later day the primary urinary fistula was closed and the final result was most satisfactory. [G.B.W.]

24.—Stubenrauch in a series of experiments on the lower animals has shown that **phosphorus** given either as a food or through the inhalation of the fumes produces in young, growing animals a thickening of the various bones especially around the diaphyses. From this it seems most probable that if this drug were given to a growing child it would increase bone-formation and therefore would be of great use in cases of rachitis. In phosphorus workers the x-rays showed some increase in the thickness of bones and a tendency towards an earlier disappearance of the epiphyseal lines. [G.B.W.]

Revue de Chirurgie.

August 10, 1900. [20me Année, No. 8.]

1. Exclusion of the Intestine. F. FERRIER and A. GROSSET.
2. A Case of Extensive Sebaceous Adenoma of the Face. G. CURTIS and LAMBRET.
3. Osteoplastic Amputation in the Continuity of the Long Bones of the Extremities. Z. SANTIRESCU.
4. Symmetrical Lipoma of the Plantar Arch. CH. FÉRÉ.
5. Gunshot Perforation of the Stomach, Colon and Diaphragm; Suture, Recovery. O. LAURENT.
6. Carcinoma of the Large Intestine. R. DE BOVIS.
7. The Anatomy of the Cecum and Appendix. G. PERONDI.

1.—A thorough discussion of the literature of exclusion with complete closure of the intestine is given. From a study of the work of others the writers conclude that the operation is one of considerable danger in spite of the successes which have been reported by 2 operators. [M.B.T.]

2.—**Sebaceous adenomas** are divided into 2 classes; the superficial form which is of interest only to the clinical dermatologist, is usually multiple and small; the large is usually a single neoplasm which may appear on any portion of the body. A case of tumor of the second variety is reported occurring in a man of 56. The tumor commenced above at a level with the upper border of the external ear and occupied the entire region of the masseter, extending to the lower border of the jaw. Its surface was entirely covered by healthy skin, which was adherent and covered with varicose veins. Complete excision was performed with an uneventful recovery, and the patient remains in good health about 6 months after the operation. On examination the tumor was found to be composed of a whitish soft tissue which was traversed by connective-tissue partitions, dividing it into a number of lobes and lobules giving it a glandular appearance. On histologic examination the whitish masses were found to be made up of epithelial cells arranged in lobular form. This form of tumor is perfectly benign, it is slow in its growth and usually single. Such tumors are of rather rare occurrence. [M.B.T.]

3.—An historical discussion of the methods of amputation is given, from the time of Celsus and Galen to the present. A method of **amputation** is described, the essential points of which are as follows: The skin and muscle incisions are made as in the ordinary classical flap-amputation. The bone is then sawed across transversely and the periosteum is separated over half its circumference. The bone is then split in frontal section in a longitudinal direction directly through the medullary canal. One-half of the cylinder of the long bone is then sawed across and removed, while the remaining half is also sawed across, but left attached by its periosteum to the soft tissues. This section of bone is then folded over, covering the exposed end of the long bone and is united by means of sutures. The amputation demands a greater sacrifice of tissue usually and takes a longer time for its performance. But amputations near joints are usually unsatisfactory, because the stump is not covered by a sufficient thickness of soft parts. By this procedure a perfectly serviceable stump is secured, which may be used immediately after healing and

never gives any inconvenience from pressure or artificial limbs. [M.B.T.]

4.—Two cases of symmetrical **lipoma of the plantar arch** are reported. One occurred in a young woman of 34, belonging to a family with a carcinomatous history, but without history of mental disease. Pressure in the mediotarsal region gave rise to intense pain on the entire inside of the foot. A second case is reported in an hysterical young woman of 38. Similar lipomas were also found in the plantar arches of her 2 sisters, but they gave rise to no disturbance. This form of tumor is thought to be very rare, and Féré believes there is indication that it is frequently hereditary. No surgical treatment was instituted in either case. [M.B.T.]

5.—A soldier of 22 was shot between the eighth and ninth ribs of the left side, about 10 cm. from the median line, with a revolver. There was severe pain in the lower portion of the chest and upper part of the abdomen, but no vomiting or expectoration of blood. From examination, it was believed that the bullet had penetrated the lung and some abdominal organ, which had given rise to peritonitis. Celiotomy was performed immediately. A perforation was found about the middle of the anterior surface of the stomach and in the transverse colon. These perforations were closed. A search was then made for the source of hemorrhage, which was evidently behind the stomach. The diaphragm was found perforated 4 or 5 fingers' breadths from the costal border, and it was closed by 3 sutures. A complete recovery followed. It is believed that death would have resulted in this case from peritonitis and hemorrhage, had not early operation been undertaken. [M.S.T.]

7.—Perondi reviews the literature of the **anatomy of the cecum and vermiform appendix**, and gives the results of a study of 50 cadavers, which he has carried out at the Anatomic Institute of Florence, Italy. He found that while the usual location of the cecum was the right iliac fossa, in 25% of the cases it was in the pelvic cavity; in 3 cases, it was in the umbilical region; in 1 case, in the lumbar fossa; in 2 cases it was absent. The axis usually inclines to the right, upward and backward, but in 3 cases it was vertical; in 2, absolutely transverse. The serosa was complete in 75% of the cases. The position of the appendix was usually vertical at the inner side of the cecum, but in 10 cases it was retrocecal. The average length was 7.6 cm.; the average diameter, 5 mm. Other details and an extensive bibliography are given. [M.B.T.]

1.—According to Sylvestre the **cardiac troubles** that have been described under the term **hypertrophy of growth** are, in reality, phenomena of nervous hyperkinesia. Their frequency is in relation to the age, the sex, the profession, and the constitution of the subject. The nervous hyperkinesia presents its maximum frequency between the ages of 13 and 16 years, and diminishes with age. These cardiac troubles are influenced by intoxications, dyspeptic and gastrointestinal troubles, and relative respiratory insufficiency from defective development of the thorax or from obstruction of the respiratory ways; but they are primarily dependent upon an hereditary or acquired neurosis. The diagnosis is made by the method of large palpation of Bard; its essential element is the differentiation of the muscular shock and the valvular vibration. Pseudohypertrophy of the heart is characterized by the presence of an exaggerated valvular vibration with its habitual characteristics of abruptness, diffusion, and variability. [J.M.S.]

2.—L. Rénon has administered **aspirin**, which is acetylsalicylic acid, in doses varying between 1 and 3 grams. In three-fourths of the cases the antipyretic effect has been immediate with a fall of from 1 to 3 degrees of temperature in the afternoon; very rarely the fall of temperature does not occur until the next day. When the aspirin is withdrawn the temperature rises again, usually to as high a degree as was noted before the use of the drug. The great inconvenience of aspirin is seen in the abundant sweats that it causes, from which a temporary weakness results that should be taken into consideration, although collapse has never been observed. On the other hand, certain patients feel very much better after the period of sweating has passed. The appetite is maintained in all; in some it has improved; the gastric tolerance has been absolute. In the discussion that followed the reading of the paper, Taisans said that he had long since renounced the use of antipyretics in phthisis, because their action is always temporary and because the drugs, often harmful to the stomach, have a tendency, when the fall in temperature is too rapid, to produce collapse. The only way of diminishing fever in tuberculous patients in a permanent manner is to submit the patients to the curative action of air. Joffroy said that he was of opinion that the fall of temperature was not the only factor in the production of collapse. He has often obtained a fall of 4 or 5 degrees in the temperature of typhoid-fever patients by the use of large doses of sulfate of quinin without accident. On the other hand, antipyrin given in small doses, while it produced a less pronounced antithermic effect, determined syncope phenomena of great gravity. [J.M.S.]

3.—The author has shown that the red blood corpuscles of birds, which are nucleated, retain the mercury in the circulation. This is in direct opposition to the behavior of mammalian red-blood corpuscles, which are non-nucleated. Furthermore, by histochemic methods the author has been able to show the presence of injected metals (iron or mercury) in the nuclei of the endothelial cells in the periesophageal membrane of the frog. Finally, in submitting a tissue to pepsin digestion, which converts the protoplasm into peptones but leaves unchanged the nucleins and the substances combined with them, he has obtained a residue in which he has been able to recover toxic substances from the animal under experiment. The nuclei of vegetable cells possess the same affinities. It would seem then that **the nucleus of the cell is the only portion of the cell concerned in absorption**. [J.M.S.]

4.—Lereboullet, at a meeting of the Académie de Médecine, held July 3, 1900, reported the case of a man, aged 38, who was a neuropathic of long standing, and whose health was profoundly altered by a **chronic diarrhea** that had persisted for 18 months, and which was accompanied at different times by intestinal hemorrhages. The condition was very refractory to treatment. When examining the patient the author was struck by the presence of multiple adenopathies that presented syphilitic characteristics. The patient acknowledged the contraction of **syphilis** 8 years previously. After 15 days of antisyphilitic treatment, which consisted of an injection of gray oil and the internal administration of potassium iodid, the diarrhea and colic had disappeared, and after a further course of convalescent treatment the patient was entirely cured. In the discussion that followed Fournier said that in a similar case the diagnosis would depend upon: (1) The syphilitic history of the patient; (2) the absence of all ordinary cause of chronic diarrhea; (3) the resistance of the diarrhea to all ordinary therapeutic agents; (4) the coexistence of other specific lesions. [J.M.S.]

5.—Maigné concludes that the only kind of **cod-liver oil** that should be used in therapeutics is the pure oil, made from absolutely fresh livers that have been carefully washed and preserved in air-tight vessels, or after they have been exposed to a temperature of not over 75° C. (157° F). The oil thus prepared has an odor similar to that of fresh sardines. It has a pale yellow color and does not leave a disagreeable after-taste that is capable of producing eructations. It is particularly indicated in tuberculosis, in convalescence from the infective diseases of infancy, in rachitis, osteomalacia, and enlargement of the lymph nodes. Its special composition, the conditions of combinations in which the component elements are found, and the ease and rapidity of its absorption make of cod-liver oil a therapeutic agent for which nothing can be substituted. [J.M.S.]

Practical Therapeutics.

Under the charge of

A. A. STEVENS, A.M., M.D.

The Treatment of Chlorosis.—Grawitz (*Therapie der Gegenwart*, June, 1900, and the *Medical Review*, July, 1900,) states that chlorosis is distinguished by the presence of a number of nervous disturbances, such as alterations in the mental disposition, and in the secretion of various organs, various vasomotor troubles, and neuralgia, which are not met with in simple anemia, even when severe. This shows that the disease does not consist in a mere alteration in the composition of the blood, and that it is probably a part of a general neurosis, rather than a primary blood disease. There is practically no deficiency in the number of the red blood-corpuscles, and the only characteristic change in the corpuscles is a diminution in the amount of hemoglobin; together with this there is an increased quantity of plasma (polyplasmia). The bone marrow is unaltered.

In the treatment the first factor is to remove the cause, if possible, by diet, change of air, or otherwise. Some cases are difficult to cure because deep-lying psychical influences, which are producing a bad effect on the developing nervous system, elude discovery and, therefore, cannot be removed. This explains the fact that a much quicker recovery is often obtained when the patient is isolated and treated in an institution than when she remains at home. At the beginning of the course absolute rest in bed is essential, even in the slightest cases, when there are no marked symptoms of cerebral anemia, such as vertigo and attacks of syncope. If the anasarca does not then disappear spontaneously, hot baths and wet packs, by producing sweating, not only diminish the edema but improve the general, and especially the cerebral symptoms. In many cases a regular course of saline purgatives is necessary. As regards diet, milk should be the chief constituent, unless the patient is obese. If there is any objection to drinking boiled cow's milk, goat's milk may be given raw. Meat and fish should be given in small but gradually increasing quantities, green vegetables, such as spinach, peas, and beans are preferable to white. Alcohol is, as a rule, to be avoided, though small quantities of beer or stout may be given if they improve the appetite. The difficulties in carrying out these simple directions in the patient's home are often very great, owing to the anomalies of appetite common in chlorosis. As regards drugs, iron is not a specific but only a useful aid in other measures. Since all preparations of iron are converted in the stomach into the chlorid before being absorbed, the new organic preparations and those made from blood and bone marrow have no advantages over the old *liquor ferri perchloridia*. Quinin and arsenic, the latter especially as arsenical waters (Roncigno, Levico, etc.), are often useful, but manganese is apparently useless. During the period of rest in bed, gentle massage of the limbs improves the circulation. In obstinate cases a course of iron mineral springs at Pyrmont, Schwalbach, Cudowa, Levico, etc., combined with an open-air life often succeeds. The climates of the Harz, the Black Forest, and of the watering places on the Baltic Sea, are beneficial, but a stay on the shore of the German Ocean often does harm. Mountain air does not agree as a rule, and to recommend it is supposed by some to increase the number of the red corpuscles; this is absurd, since it is the amount of hemoglobin, and not of red corpuscles, which is deficient. Though excellent results are usually obtained by suitable measures, in a minority of cases no treatment avails. The patients are then usually thin, delicate, and poorly developed generally; they suffer from the hypoplasia of the heart and large arteries described by Virchow; and generally eventually die of some intercurrent disease. This failure to develop is often due to the senseless custom of dressing children in corsets and "elegant" clothes, which impede free muscular movements. Sweets, unsuitable food, overwork at school, and late hours also contribute to the developmental failure.

The Palliative Treatment of Paralysis Agitans.—Williamson (*Practitioner*, April, 1900) states that, as all forms of nervous excitement increase the tremor, it is important that the patient should lead a quiet life, and be spared from

all forms of mental excitement and worry as much as possible. A warm bath will often cause a diminution of the tremor for several hours. Alcoholic drinks and strong tea and coffee cause the tremor to increase. It is important that the patient's room should be well ventilated, and not too warm, as a warm stuffy room makes the restlessness worse. In the open air, the patient usually feels better, and one of the best means of relieving uncomfortable sensations and restlessness is life in the open air. During a railway journey or drive in a carriage, the trembling is diminished, and the same occurs when the patient is wheeled about in a chair. The only drug that the author has found of real service is hyoscin hydrobromate. Small doses ($\frac{1}{160}$ to $\frac{1}{125}$ grain) are of no value; the practitioner should begin with $\frac{1}{125}$ or $\frac{1}{160}$ grain, by the mouth, and cautiously increase the amount. When the patient can take $\frac{1}{2}$ grain in 2 drams of chloroform-water, good results follow. Williamson has given to one of his patients $\frac{1}{2}$ grain three times daily, with short intermissions, for 3 years. If the patient suffers from insomnia, a little whisky and water may be given at bedtime, or sulfonal may be employed. Hyoscin, however, is also useful; a dose of $\frac{1}{2}$ grain in chloroform-water should be put at the bedside of the patient, to be taken soon after going to bed, if sleep does not occur, or if the patient wakes very early in the morning, and cannot get to sleep again.

The Treatment of Empyema.—Martin (*Therapeutic Gazette*, August 15, 1900) summarizes the treatment of empyema as follows: Empyema is best prevented by promptly evacuating all considerable inflammatory effusions. In the diagnosis of these effusions, by means of exploratory aspiration, the skin should be punctured by a tenotome at the point where the needle is to be driven in. Serous effusions are best evacuated by aspiration. If they reaccumulate after the third evacuation, they should be subjected to continuous siphon drainage, the puncture being made by a small trocar and canula, the latter being of such size that a small drainage tube may be slipped through it. Recent empyemata are best treated by continuous siphon drainage, the tube being introduced through a canula of at least the diameter of the little finger. When, because of a narrow intercostal space or because of constant blocking with fibrinous material, siphon drainage thus provided is inadequate, an inch of one of the ribs (usually seventh or eighth) should be resected, and a drainage tube the diameter of the thumb should be used. When the conditions are such that it is obviously impossible for the lung to expand under the influence of siphon drainage and respiratory exercises, Delorme's operation of stripping the pseudomembrane from the compressed lung should be attempted. When Delorme's operation is impracticable, a resection of the ribs (Elander) or of the chest-wall and thickened pleura (Schede), corresponding in extent to the size of the underlying cavity, is indicated.

Opothopathy.—Mosses (*American Journal of the Medical Sciences*, September, 1900) concludes with some practical deductions with regard to the value of opothopathy, which he distinguishes as direct and indirect. The writer believes that ovarian extract is most useful in relieving preclimacteric disturbances, although it is also indicated in the reflex troubles following the establishment of the menopause. Menstruation that has been prematurely arrested reappears after the use of the drug, but it has no influence in exciting the menstrual flow in young girls who have the *nixus* without any discharge of blood. In discussing so-called indirect opothopathy, he states that in cases of amenorrhea due to anemia iron is preferable to ovarian preparations, while he is confident that they have no value in the treatment of osteomalacia as compared with castration.

Orexin Tannate.—Zeltner (*Bulletin Générale de Thérapeutique*, November 8, 1900), states that he has employed orexin in more than 50 cases as a stimulant to the appetite. In 30 of these cases the remedy proved highly efficacious. In 13 cases of phthisis excellent results were obtained in 10. In 7 cases of uremia there was marked improvement of the appetite in 5. The dose of orexin tannate is 5 grains, twice daily, 2 hours before meals. The tannate has the advantage over preparations of orexin in not causing any burning sensation in the stomach. The drug appears as a yellow powder, insoluble, tasteless, and odorless.

NEURASTHENIA.¹

By J. T. ESKRIDGE, M.D.,
of Denver, Col.

Neurologist to St. Luke's Hospital, Consultant Alienist and Neurologist to Arapahoe County Hospital.

NEURASTHENIA, the subject which has been chosen for me tonight, unfortunately, is too familiar to all of us. Under another name, the "irritability of weakness," it was known scores of years ago. Simple neurasthenia, especially in the beginning, is not a disease, but a condition. We speak of neurasthenic states, referring to a weakened, and hence, an irritable condition of the central nervous system. It differs in this respect from hysteria, which is a disease, a neuropathic state.

In health the higher nerve centers control and inhibit to a greater or less extent the lower centers of motor and sensory function, and of organic life. In prostration, exhaustion, and impoverished states of the nervous system, these controlling centers are to a greater or less extent deranged, and their controlling functions may be almost completely lost, hence the lower centers that formerly worked under the guidance and control of the higher are allowed to run at their own "sweet will." Stored energy in the higher or cortical centers, in exhausted states, is given off prematurely and irregularly on the reception of impressions that would, under healthful conditions, elicit but little response. It is seen then that exhaustion of the entire nervous system, known as neurasthenia, is a condition of weakness and irritability.

We have neurasthenia existing under various and variable conditions. Primary neurasthenia is a condition in which the exhaustion and irritability of the nervous system constitute the chief derangement of health. Secondary neurasthenic states follow diseases that have induced neurasthenia. These may be gross organic lesions, acute exhausting diseases, or even hysteria. In neuropathic subjects neurasthenia may cause hysteria, and such a condition may be regarded from a clinical standpoint as atypical of the latter disease. Hysteria may give rise to a neurasthenic state, but it never runs into a condition of typical simple neurasthenia.

If I have made myself clear thus far, I have meant to say that simple primary neurasthenia is not a diseased state, but an exhausted and irritable condition of the nervous centers, whereas, on the other hand, hysteria is a neuropathic condition and is almost invariably developed upon a neuropathic state of the central nervous system. The two diseases in their typical forms are cleanly cut in their symptoms and readily differentiated from each other.

Etiology.—Any influence, either hereditary or acquired, that tends to exhaust the nervous system may predispose to the development of neurasthenia, and anything that exhausts to the point of derangement of the nervous system may directly give rise to it; thus some causes may be both predisposing and exciting. The greatest predisposing cause, in all probability, is heredity, although this does not play as important a part in the causation of neurasthenia as it does in hysteria. Neuropathic states, such as insanity, epilepsy, or organic

nervous diseases in the ancestry are much more likely to predispose to hysteria than to neurasthenia, but those conditions in parents that tend to weaken the nervous system in the offspring without being carried to the point of disease, are the hereditary influences that predispose to neurasthenia. Nervous weaknesses, irritability, tuberculosis, syphilis, gout, alcoholism, and extreme age of the father may act as predisposing causes. Among the acquired predisposing causes are, unwise, loose, unsystematic and impracticable methods of education; forcing children in their educational work without paying sufficient attention to exercise and the observances of the laws of health; paying too much attention to music and drawing, to the exclusion of outdoor exercise. But it can be readily seen that the causes here classed as predisposing may, when carried to an extreme degree, give rise to neurasthenia, and thus act as an exciting cause. Occupations attended by worry, undue excitement, uncertainty, give rise to undue wear and tear, and may predispose to exhaustion and irritability. Neurasthenia is more common in the single than in the married state. The reason for this is not far to seek, when we remember that the male is not free from the irregularities of life, and the indulgences that tend to exhaustion. In the female the unequal battle for existence is a potent cause. The majority of neurasthenics are found between the ages of 20 and 50. The Hebrews and Slavs are the races most predisposed to the condition under consideration.

The exciting causes are both physical and psychical, but the latter far outweigh in importance the former. The greatest exciting cause of neurasthenia known is probably trauma, but trauma unattended by psychical shock is rarely followed by typical neurasthenia. Injury in a railroad accident, electrical shocks and explosions of various kinds, in which the mental excitement and shock are intense, are the ones which give rise to the most desperate cases of neurasthenia. It is possible that over-physical work, especially if it is uncongenial, exacting, and requires undue length of hours, will exhaust, not so much probably on account of the work itself, as on account of the worry incident to it. Excitement of a depressing character is much more potent in the causation of neurasthenia than that of a pleasurable nature. We often see the influence of mental depression, anxiety, and apprehension illustrated in the mother, who for days or weeks watches over her sick child. She comes out of the ordeal tired, nervous, and exhausted. The trained nurse, on the other hand, who gives longer hours, better service, and attends case after case, year after year, is rarely afflicted with neurasthenia. One does her work as a professional, the other exhausts herself from depressing mental emotions. Anything, I repeat, that exhausts the entire nervous system may give rise to neurasthenia. Excessive child-bearing, prolonged lactation, acute illness, such as typhoid fever, diphtheria, malaria, and influenza, are potent causes. Excessive alcoholic indulgences, sexual excesses, or abnormal methods of gratifying the sexual appetite may either predispose or give rise to neurasthenia. Tea, coffee, and tobacco have been blamed for the development of neurasthenia. I am inclined to think that the excessive use of these articles may predispose to neurasthenia, but in the absence of other depressed conditions, it is unlikely that they are capable of causing the development of so exhausted a state of the nervous system. I wish to call especial attention to the organic and functional diseases that may give rise to neurasthenia,

¹ Read before the Denver and Arapahoe County Medical Society, March 26, 1900.

because, when I come to speak of treatment, especially of the prevention, I shall have occasion to refer to these again. Among these are indigestion, intrapelvic troubles in the female, diseases of the genitourinary organs, tuberculosis, anemia, chlorosis, cardiac and renal diseases, or any organic disease or functional disturbance that may lead to the exhaustion of the nervous system. It is important to bear this in mind, because it is easier to cure curable organic or functional disease before it becomes complicated with neurasthenia.

The diseases of the ear and nose rarely act as an etiologic factor in neurasthenia more than as a contributory cause, except, possibly, in extreme cases in which severe and prolonged irritable affections of these organs may so wear upon the nervous system as to cause the development of a neurasthenic state in persons who are naturally very nervous. Prolonged disorders of the teeth and eyes on the other hand are undoubtedly capable of giving rise to neurasthenia. I have seen a number of cases of neurasthenia in which the exciting cause appeared to be prolonged irritation caused by defective and painful teeth. The immediate exciting cause in these cases has always been a prolonged siege with the dentist. There are several affections of the eyes that may give rise to neurasthenia, but the greatest one is uncorrected refraction errors. Persons who are suffering from uncorrected astigmatism, anisometropia, and exophoria, and are compelled to use their eyes for close work, soon become nervous, irritable, and suffer a great deal with headache. If the eye-strain is not relieved the nervous irritability finally leads to extreme nervousness and weakness, so that the sufferer may become a typical neurasthenic from prolonged eye-strain.

Pathology.—The observation of Dr. C. F. Hodge showed that prolonged exercise to the point of physical exhaustion is followed by change in the ganglion cells of the spinal cord of certain insects and animals, and that of Mosso that toxic agents were found in the blood of animals which were physically exhausted. The well-known experiment of physiologists,—exhaust a muscle by electrical stimulation until it refuses to respond, then wash it out by injecting into its artery normal salt solution, the exhaustion disappears and the muscle reacts to the electrical current,—shows that some agent is developed in the blood, as a result of muscular exhaustion capable of giving rise to depressing influences. It is probable, then, that the pathology of neurasthenia consists in cellular changes, so that function is perverted, and in the development in the blood of poisonous agents, which the various excretory organs, on account of the depressed state of the nervous system, are no longer able to throw off.

Symptomatology.—The symptoms of neurasthenia will be more readily appreciated if we remember that the condition is attended with an exhausted and irritable state of the entire nervous system. We have conditions in which the head symptoms seem to predominate, and others in which those relating to the spinal cord are most prominent, but this is probably not because one portion of the nerve centers suffers, while another escapes, but is due to the fact that the cause which has given rise to the exhausted condition has acted directly upon the center that seems to suffer most. We see this in traumatic neurasthenia, in which the head, spine, or some other portion of the body has sustained a blow.

Some years ago Dr. E. G. Whittle of London, published a small brochure, entitled "Congestive Neuras-

thenia," or "Insomnia and Nerve Depression." Dr. Whittle would have us believe that we have states of nervous exhaustion attended by congestion of the brain, in which blood-letting is the sole agent in the treatment. I have carefully read the booklet referred to, and studied the cases. I am quite thoroughly convinced that the title of the book is wrong; that it might better be termed "Secondary Neurasthenia following Organic Intracranial Disease." Some of the cases that he relates are typical of neurasthenia, but these are the ones that did not improve on local abstraction of blood from the head. In speaking of this class of cases, he says:

"My present object is to draw attention to the fact, which I have proved again and again in my own practice, that there are many cases of nerve-depression which can only be successfully treated by bleeding, saline aperients, low diet, and no stimulants, though they are usually treated by directly opposite remedies. The description already given will serve to identify the cases with precision, and distinguish them from allied types. The absence of anemia and neuralgia, the presence of melancholia without delusions in healthy people, insomnia, suffusion of face, neck, and conjunctivae, vertigo and other abnormal feelings about the head, visible arteries and full veins, with intolerance of stimulants and iron tonics, fairly characterize the type. Many are as intolerant of chloral and opium as of iron and stimulants. Instead of soothing and producing sleep they may excite and provoke the greatest distress, especially where the signs of brain-congestion are prominent, viz., heat of head with throbbing vessels, abnormal feelings *all over* the head, as aching, tightness, fullness, pressure, bursting, etc." If I had time to quote from some of the published cases, I think that you would agree with me that Dr. Whittle is dealing with intracranial disease instead of neurasthenia pure and simple.

As the disease under discussion is attended with an exhausted state of the whole nervous organism, and hence every organ of the body is functionally deranged, and of this derangement the patient is painfully conscious, it follows that the symptoms are numerous. They may be divided into four groups: Motor, sensory, mental, and visceral. After giving a short résumé of the symptoms, I will take up a few of the most prominent of each group, and discuss them a little more in detail.

This affection is attended by a sense of exhaustion and lack of nerve force, but not by abolition of power, sensory or motor, such as we find in hysteria. There is a lessened power of physical and mental endurance. The patient may temporarily show a considerable amount of muscular power, but this is soon exhausted and may be followed by hours or days of increased fatigue. Every outlay of energy is paid for on the part of the patient by hours of suffering and exhaustion. Lack of mental endurance is shown by the fatigue that follows reading or any other mental effort. There is a mental and physical irritability, annoying to the patient and often exasperating to the physician. There is frequently a sense of great physical and mental depression, often attended with doubt, hesitancy, and great apprehensiveness. Sometimes the depression is so great as to make the physician suspect a psychosis, such as melancholia; indeed, it is not infrequently difficult to draw the line between melancholia and neurasthenia with great mental depression. Emotional manifestations, such as shedding tears, and outbursts of laughter, are not infrequent.

Most authorities agree that insomnia is one of the most troublesome symptoms of neurasthenia. Pain and hyperesthesia are common symptoms. The pain is most prominent in and around the spinal column, in the neck and in the head, but it may be complained of in almost any portion of the body. Pressure over the painful regions of spine or over areas of hyperesthesia is usually attended by increase of the pulse-rate. In nontraumatic cases the pain is usually most severe in the upper portions of the spine and in the back of the head. In the traumatic ones, the lumbar region is usually the seat of the greatest pain and tenderness. Paresthesia, such as burning, "pins and needles" sensation, and crawling, is not infrequent in neurasthenia. While hyperesthesia is common, anesthesia does not occur. If the latter symptom is present the case is looked upon as one of hysteria. Central vision is usually normal, but the peripheral fields soon become exhausted, when the fields appear narrowed. Asthenopia is usually present. Auditory hyperesthesia is a common symptom. The motor symptoms consist of lessened power and lack of endurance for muscular effort continued any length of time beyond a few moments. There is neither paralysis nor contracture such as is found in hysteria. The deep reflexes are increased, the superficial normal, lessened, or increased. The trophic changes usually relate to those attendant on general malnutrition. There is nothing in the respiratory changes that is of much diagnostic value. The pulse-rate, on the other hand, is of great importance. This is, as a rule, considerably increased, and is often greatly accelerated on the slightest exertion or the least excitement. Knapp says: "One of the most striking features of traumatic neurasthenia is in the rapidity of the pulse. In 25 cases it ranged from 72 to 140, the average being 95, and in only 3 cases did it fall below 80."

Motor Symptoms.—There is no absolute paralysis, but muscular power is lessened. At the first effort the patient makes he may exert considerable force; rarely is this up to the normal, but his power soon becomes exhausted, so that at the latter part of a prolonged examination he may not be able to register on the dynamometer more than half what he could at the first of the examination. He complains of muscular fatigue, and frequently the muscles of the legs and arms are the seat of pain, especially after he has exerted his muscles to any extent. He may start off and walk with a fairly good gait for a while, but he soon becomes exhausted. The muscles themselves show no electrical change, but they may become flabby from the want of use. Wasting in them does not amount to much. Sometimes the muscles are the seat of a tremor, especially on exertion. This is much more common in the traumatic cases than in the nontraumatic ones. Muscular jerking, especially of groups of fibers in the muscles, is occasionally met with. The superficial reflexes are rarely much exaggerated. I cannot say that I have seen greater changes in the superficial reflexes of neurasthenic subjects than I have found in persons who were in an apparent state of health. On the other hand the deep reflexes are often considerably increased; especially do we find this in the knee-jerks, where tapping above the patella frequently gives rise to a smart contraction of the extensor muscles of the thigh. The front tap contraction is frequently present, and spurious ankle clonus is often met with, but I have never seen a case of true ankle clonus in simple neurasthenia. Dr. Dercum, so far as I know, is the only writer that speaks of the knee-jerks becoming exhausted in neurasthenia after repeated tapping of the

patella tendon. I have repeatedly tested this phenomenon, and have elicited the knee-jerk in typical neurasthenics from 15 to 20 times in rapid succession, the knee-jerk being as strong, if not stronger, at the last of the experiment, as it was the first time that I elicited the muscular contraction. The deep reflexes of the arms are usually increased, and frequently percussing the muscle, either at the nerve point or on the body of the muscle, will elicit smart contraction. There is no distinct ataxia in neurasthenia, although there is frequently a slight unsteadiness of gait, especially on the patient's first rising. This is probably due more to disturbances in the cerebral circulation than to incoordinate movement of the muscles. Dizziness or vertigo is common in many cases of pronounced neurasthenia. It is not so great as it is in cerebellar disease, but sufficiently developed to annoy the patient in descending stairs, in suddenly rising from the recumbent to the erect posture, in quickly turning around or in walking over uneven surfaces.

Sensory Symptoms.—When it is remembered that the functions of the whole nervous system and frequently of every organ of the body is perverted to a greater or less extent in neurasthenia, it can be readily understood that there is a multiplicity of subjective sensory symptoms. They are often so great that the patient in despair will say, "Oh! I don't know of what I suffer, I simply suffer from everything; I am out of sorts all over;" others say, "I am simply nervous; I do not suffer from anything but nervousness." On careful inquiry it is found that there are often vague pains in the head, and curious sensations in the scalp, as of worms crawling, or there is a band-like sensation around the head, but the most common cephalic sensation is suboccipital pain, pain in the upper portion of the cervical region and occasionally across the forehead, just above the eyes. The headache at times is little more than an uncomfortable sensation, at other times it is quite severe, so as to prevent sleep. Backache is common, the ordinary backache is most commonly complained of in the lumbar region. The pain is not infrequently found in the mid-scapular region and in the sacrum. When the back is the seat of severe pain, it is more commonly found in the upper dorsal and cervical regions in non-traumatic cases and in the lumbar region in the traumatic ones. Not infrequently there is a condition of hyperesthesia of the entire spine, a slight touch giving rise to severe pain. Sometimes pressure will relieve the superficial pain. When pain is deep-seated in the back, pressure will often give rise to considerable acceleration of the heart's action. Pain and fatigue are often complained of in one or more limbs, especially in the legs. Cutaneous hyperesthesia, but never anesthesia, is found over various portions of the body; such as on the sides of the trunk, in the epigastrium, over the scalp, nipples or testicles. While there is no anesthesia, numb sensations are frequently complained of.

The eye-symptoms found in neurasthenia are simply indicative of weakness and irritability. Central vision is usually good, but the peripheral fields are easily exhausted. If the field is taken by testing the periphery before the central, and then again taken by beginning at the central portion and going from within outward, it will be found that the field, by the second examination, is much smaller, owing to exhaustion of the peripheral portion of the retina, than that taken by testing the peripheral field first. It is often found that the muscles of the eyes are weak, reading tires the patient and often

gives rise to headache. This is frequently found when the refraction of the eyes is emmetropic. Vague subjective sensations of vision are not infrequently complained of. There may be sudden blurring of the sight; things may look as if seen through a smoked glass; a condition of hippus, that is, a dilation and contraction of the pupils, following each other in rapid succession, when the eyes are exposed to the light, or even in a darkened room, is not infrequently found, and is said to be usually associated with exaggeration of the knee-jerks. Temporary inequality of the pupils is not uncommon, but it is always temporary in character. The disorders of hearing, while not serious, are often very distinct. They consist of hyperesthesia and tinnitus. The patient's hearing is frequently so exaggerated that ordinary sounds become painful, and sounds barely appreciable by the normal ear are heard quite distinctly by the neurasthenic. The tinnitus sometimes becomes quite distressing. The sound may be buzzing, whistling, roaring, pulsating, or ticking in character. Disturbances of smell and taste, although the former is less frequent than the latter, are not great. There may be a condition of hyperesthesia or paresthesia of these senses. When the sense of taste is greatly perverted it may decidedly interfere with taking food.

Mental Phenomena.—There is always a lessened power for mental work. The ability to maintain mental concentration is lost, and the patient seems unable to remember scarcely anything that he reads, while in fact, owing to the inability for mental concentration, he has simply perceived, and has not appropriated what he has read. His memory is good for what his mental power has been able to grasp and appropriate. Neurasthenic patients frequently complain of loss of memory, and the supposed mental failure is a great source of worry to them, whereas, in fact, as evidenced by their ability to detail every minute subjective symptom proves that their memory is nearly perfect. Mental fatigue frequently follows the slightest exertion; so-called will-power, courage, and confidence are lessened. The patient becomes vacillating. On account of his inability to perform his usual amount of mental work, he becomes at first irritable, then sensitive, and finally greatly depressed, so that his condition seems very much like that of one in the earlier stage of melancholia; but even in this condition he is easily provoked to fits of laughter on witnessing some ridiculous thing, or is easily made to cry on reading accounts of some depressing subject. While he may maintain, on account of introspectiveness and depressed state, that he is suffering from this or that disease, on the assurance of his physician that he is free from this morbid state, he accepts the assurance, thus distinguishing his condition from the melancholic, whose delusions cannot so readily be gotten rid of. As neurasthenia continues, he loses, to a certain extent, the sense of propriety and is ready to discuss symptoms relating to the sexual organs in the presence of nonmedical persons. His affection for near relatives frequently lessens. His children, that before had been his delight, often annoy him, and he is given to seclusion. He may become the subject of the various phobias, or may be depressed with a sense of great fear of some approaching danger. A sudden and depressing mental impression made upon him may so affect him as to cause a relaxation of the sphincters of the bladder and bowels. Sleep is nearly always disturbed in well-marked cases of neurasthenia, and sometimes insomnia becomes the most prominent symptom. There may be

days and nights together when the patient gets but little sleep, unless assisted. Often the sleep obtained is only gotten by slight naps, which are frequently disturbed by unpleasant dreams.

Visceral Symptoms.—The most constant and important of these relate to the digestive organs. In rare instances we are consulted by neurasthenics, who claim that their digestive organs are in a perfect condition, but on questioning closely it is found that there are many evidences of disturbed digestion and assimilation. We must ever bear in mind that the neurasthenic state may be secondary to the disorders of digestion. Be this as it may, the condition of the digestive organs is of the first importance. There may be a condition of atonic dyspepsia, in which the appetite is capricious and digestion slow, imperfect, and attended by flatulency. In a few cases there is the condition of hyperesthesia of the stomach. The patient experiences a burning sensation in the stomach when it is empty, but is relieved as soon as he takes food. This is always attended with an uncomfortable sensation across the forehead and a sense of fatigue. In those cases in which there is no hyperesthesia of the stomach, gases on eructations, distention of the bowels and constipation, with an uncomfortable sensation in the stomach an hour or two after eating, are the most prominent symptoms. In another class of cases there seems to be a gastric catarrh, in which digestion is slow and imperfect and attended with acid eructations after eating. Sometimes the gas eructations are so violent that some of the contents of the stomach is thrown back into the esophagus, giving rise to what is commonly called heart-burn. Sometimes the esophagus from the throat to the stomach is the seat of a burning sensation. Constipation, sometimes alternated by diarrhea, is common. In a few cases mucus is passed by the bowels, and sometimes a fibrous substance may pass with the stools. In all severe cases of neurasthenia a stool is followed by a sense of prostration. There is not that feeling of buoyancy and of well-being which follows similar evacuations in a healthy subject. When the stomach is greatly distended with gases, pain is felt in the precordial region, in the stomach, frequently at the transverse flexion of the colon on the left side, and sometimes in the region of the iliocecal valve. The circulatory disturbances consist of cardiac palpitation, precordial pain, an occasional attack of false angina (rare). The pulse in the false angina is rapid, and sometimes almost imperceptible, especially during the second stage, when there is constriction of the arteries, differing from the pulse of a true angina, in which it is slow. The pulse in neurasthenia is almost invariably rapid; especially is this found on exertion, and in cases of tender spine or lumbago, typically met with in traumatic cases; pressure on the painful region causes considerable acceleration of the pulse-rate. Flushing of the limbs and face is common, and sometimes there is a throbbing of the larger vessels. The feeble circulation is shown by cold hands and feet, and occasionally by lividity of the extremities. In some cases there may be flushing with general perspiration, but in others the skin is dry and harsh. The urine is often scanty, because the patient imbibes too little fluid. It is sometimes cloudy when it is first passed, leading one to believe there is some vesical irritation. The phosphates are often increased, and oxaluria is sometimes met with. Transient glycosuria or albuminuria has been observed.

Perverted functions of the sexual organs are common. These consist, in the male, in nocturnal emissions, pre-

mature ejaculation, and greatly impaired, or loss of, sexual power. These symptoms relating to the sexual organs may constitute the main ones of which the patient complains. They are a great source of worry to him, and in some cases lead to great mental despondency. In the female, sexual organism may occur during sleep, attended with voluptuous dreams, and followed by a sense of great prostration. There is often hyperesthesia or paresthesia in the sexual organs of both sexes.

Diagnosis.—The principal diagnostic symptoms of neurasthenia are the following: Exhaustion, without complete loss of power; insufficient reserve force to enable the patient to recuperate rapidly after he has been compelled to exert himself, either mentally or physically; intense self-consciousness and a habit of introspection. The patient is cognizant of the perverted function of nearly every organ in the body. Numerous subjective sensory disturbances, mental depression, and apprehensiveness, undue emotional manifestations, irritability, and rebellious insomnia are often present. Pain and tenderness over the back; in the traumatic cases they are most intense over the lumbar region; in the nontraumatic, they are most pronounced in the upper region of the spine or at the junction of the spine and skull. There is hyperesthesia and paresthesia, without anesthesia; muscular weakness and fatigue, without paralysis or contracture; narrowing of the fields of vision after exhaustion of any kind, especially after the retina has become exhausted from repeated examinations of the visual fields. Auditory hyperesthesia exists and the deep reflexes are increased. The accelerated pulse-rate is greatly influenced by exercise, pressure over the tender spots, exhaustion, irritation, or excitement. Vasomotor disturbances, such as profuse perspiration over the entire body, or over a portion of it, are not uncommon. It is rare to find a case of neurasthenia unattended by more or less disorder of the digestive organs.

After having satisfied ourselves that we have a case of neurasthenia with which to deal, the next point to determine is whether it is associated with some organic disease, and secondary to it, such as intrapelvic, genitourinary disorders, etc. We must remember that neurasthenics may become hysterical, but that hysterics, while they may be neurasthenic, never become neurasthenics pure and simple. In neurasthenia there are no paralysis, contracture, anesthesia, and convulsions, while all of these symptoms are common in hysteria. Neurasthenia, as a rule, develops gradually; hysteria, on the other hand, may develop rapidly, especially after some emotion or shock. In hysteria we further have the globus hystericus, the peculiar pain in the top of the head, which has received the name of clavus and reversal of the color-fields. These are all absent in neurasthenia. In hysteria the symptoms not infrequently change from day to day. This is not the case in neurasthenia.

In well-developed cases of neurasthenia and melancholia, there is no difficulty in making a differential diagnosis between the two conditions. In the incipient stage, before any delusions are apparent, in melancholia, the diagnosis is sometimes attended with great difficulty. The difficulty is increased by the fact that most melancholics are neurasthenic to a greater or less degree. In a neurasthenic, the impression that this or that organ is diseased, that he is suffering from some incurable disease, the idea can be eradicated by repeated assurances to the contrary; but in a melancholia, the

presence of delusions that will not be persuaded away, and out of which the patient cannot be reasoned, is the only absolute and reliable symptom in the differential diagnosis. In melancholia there are delusions more than temporary in character; in neurasthenia there may be temporary ones. In melancholia sine delirio the diagnosis becomes exceedingly difficult, were it not for the fact that these cases do not present typical symptoms of neurasthenia.

In some cases there is a similarity between the early symptoms of parietic dementia and neurasthenia. Neurasthenics may show tremor; alteration of speech; change in the handwriting, and inequality of the pupils. The distinguishing points are these: that in a neurasthenic, speech is imperfect on account of lessened will-power and vigor, but on his making an effort, especially in the early morning, he can speak distinctly without any evidence of alteration of speech; his changed handwriting is most commonly found in letters to relatives and friends; but when he is compelled to write a business letter of importance, he does this almost as perfectly as he ever did; the inequality of the pupils is of only temporary duration; the defective memory is imaginary, rather than real, as he can relate his symptoms minutely, and shows no lack of memory for things which pertain to himself, and can detect his mistakes and correct them; he is seclusive, the parietic element is obtrusive.

Lastly, how are we to determine, especially in medico-legal cases, whether a supposed case of neurasthenia is genuine or real, or whether the neurasthenic state existed prior to the accident to which the claimant attributes all his ills?

Neurasthenia is gradual in its development. It takes time for the entire nervous system to become exhausted. It is possible for incipient neurasthenia to manifest itself soon after an accident; but unless the trouble is promptly relieved, the symptoms will increase for months, until the condition becomes pronounced. If, then, a condition of neurasthenia is fully developed a few days after an accident, it is quite evident that the accident could have had little more to do with the neurasthenia than to render it more pronounced. In other words, the neurasthenic state must have existed before the accident.

In answer to the other question, how are we to determine whether the neurasthenia is genuine or feigned? It is not always easy to satisfy ourselves on this point. But a slow or normal pulse-rate is against the existence of pronounced neurasthenia. A pulse-rate that is not considerably increased by exercise or by pressure over hyperesthetic areas, especially over a tender spine, is very decidedly against the presence of traumatic neurasthenia.

Prognosis.—The general prognosis of neurasthenia is, on the whole, comparatively good; but notwithstanding this general statement, many cases go through life complaining and never enjoy good health. These, however, are those who have never had a strong constitution, and have had to battle with life very much hampered from weak, nervous organizations. The principal unfavorable conditions in the prognosis are, heredity, especially relating to neurasthenia and general nervousness in the family; neuropathic inheritance; a tendency to neuropathic degeneration in the patient; the development of the condition in early life and beyond the age of 50 or 60; and long duration of the neurasthenic state. We have to remember, also, the great danger of the neurasthenic forming a drug habit. There is no doubt but some cases of neurasthenia pass into a psychosis.

Treatment.—One of the most important points in the treatment of neurasthenia is prevention. But little so far has been said concerning prevention of neurasthenia, but if we study our cases and find how many of these neurasthenics develop after intrapelvic troubles, gastric disorders, diseases of the genitourinary organs, or apparently result in persons in middle or advanced life from their taking up occupations which compel them to give up active life and lead a sedentary habit, and to fill positions for which they are unfitted from defective training and deficient education, we shall realize how important it is to remedy the conditions that ultimately lead to the prostration of the individual. Intrapelvic troubles should not be allowed to go on unrelieved until they have resulted in the patient's prostration. Neither should any disease be allowed to prey upon the patient until his vitality is greatly lessened. I have in mind, at present, a strong and vigorous man, who has led an active life, ridden his wheel or a horse 20 or 30 miles every day for a number of years. He has recently accepted a position of great responsibility which requires his closest attention and compels him to give up all active exercise. At present he is rapidly developing the symptoms of neurasthenia and is now planning to take a rest. These cases are not infrequent. It is not work that kills, but worry. Any occupation that is attended by worry, or excitement of a depressing character, is a dangerous one. What will worry and excite one person may be done by another, who is better fitted for it, with the greatest ease, and is unattended by exhaustion.

As indicated under the head of Etiology, affections of the eyes, ears, nose, and teeth, if unrelieved, act as causes in the development of neurasthenia, therefore, these organs should be carefully examined, errors of refraction corrected, the decayed teeth repaired or extracted, and other diseases treated, if possible.

The treatment of the neurasthenic condition, after it is developed, consists of rest, partial or almost absolute, diet, and in many cases isolation. For those who are in the early stages of neurasthenia, with a fair constitution, partial rest, with fewer hours of business, and relief from some of their responsibilities may be attended by a complete recovery. Others require not only partial rest, but absence from business for prolonged periods. In many cases, especially in the profound neurasthenics, but little can be accomplished without rest, as nearly absolute as can be maintained. The patient should not be allowed to feed himself, the discharges from the bladder and bowel should be passed into receptacles in bed, and a nurse should wait upon him as completely as though he were suffering from some acute disease. The digestive organs should receive attention and a suitable diet, skimmed milk being the best, beginning with a small quantity, 2 or 3 ounces every 3 or 4 hours for the first few days. It is rare that a patient after he becomes hungry cannot take and digest a small quantity of milk. As soon as the digestive organs will permit of it, the milk should be increased to the point of toleration, but it should never be carried so far that the patient becomes disgusted with it. As soon as it is possible to do so, a part of a meal can be given, finally a full meal a day, followed later by three full meals each day. By systematically and gradually increasing the feeding, several pounds of flesh can be put on the patient. At the same time that the rest cure is being undergone the nutrition of the muscles should be kept up by massage and electricity.

In most cases of neurasthenia, especially of the severer

forms, isolation is necessary. They should be allowed to see no one, except the physician and nurse, until such time as, indicated by their improved condition, they show that they are able to see their relatives and friends without becoming depressed or talking about themselves. Absolute rest should never be carried to such an extent that the patient becomes bedridden. When the patient begins to beg to be allowed to remain in bed, it is time to get him out.

I have already occupied more time than I had intended, and must leave the details of the treatment to be brought out by members of this society in the discussion.

MENTAL DISTURBANCES AFTER OPERATIONS UPON THE EYE.¹

By WILLIAM CAMPBELL POSEY, M.D.,
of Philadelphia.

DELIRIUM following the extraction of cataract is of not rare occurrence. Despite its comparative frequency, however, the subject has received but scant mention in all textbooks upon ophthalmology, and there is a wide difference of opinion among authors regarding its causation.

Having but recently encountered some cases of this nature I determined to report these, together with a series of similar cases from the Wills Eye Hospital records, with a view to ascertaining what the causation of the delirium might be, and what were the best measures to adopt for its prevention and relief.

Disturbances of the mind after operations upon the eye usually follow the removal of cataract; they have, however, been occasionally observed after various other surgical procedures in ophthalmology.

The mental derangement, as a rule, takes the form of a delirium which appears usually upon the evening of the third day after the operation and continues a few days to a week, according as the surgeon is prompt in combating it, and fortunate in his choice of remedies. Although frequently retarding the healing process by the irritation which is provoked in the eye at the height of the delirium by interference with the dressings, etc., the ultimate success of the operation is not as a rule marred by its occurrence. It is rarely seen in the young, but it is met with in those who are well advanced in years, and according to the majority of observers, especially in those who are predisposed by heredity, alcoholism, or some other cause to mental aberration. Schmidt-Rimpler also thinks that it rarely occurs in individuals in the best walks of life.

During the performance of the operation and for the first few days after it, the behavior of the patients is usually all that can be desired. At the end of the second or third day, however, towards evening, the patients become restless and wish to rise out of bed, and if unrestrained would tear the dressings from the eyes. Rapid and violent delirium may supervene. Such patients usually fancy the room on fire in which they are confined, and would make their escape at all hazards. Not rarely they imagine they are subjects of persecution; that they are being pursued or unjustly confined, and they demand a knife with which to wreak vengeance upon their oppressors. Although the symptoms usually are more apparent at night, the patient

¹ Read before the section in Ophthalmology of the College of Physicians of Philadelphia, January, 1900.

rarely recovers his full senses during the day. Hallucinations are not always present, but there is usually some fixed idea which predominates. Pain in the eye is but rarely complained of, and rise of temperature is accidental and not constant. After a few days the delirium subsides and the mental faculties are slowly regained without leaving any permanent mental aberrant processes.

The description of the delirium which has just been given corresponds to that which occurs in most cases, although it may assume a variety of forms, largely according to the individuality of the subject affected. Thus, Frankl-Hochwart has divided these psychoses into four groups: 1. Hallucinatory mental derangement in non-alcoholics. In this class the commencement of the affection is usually on the first day after the operation and occurs in individuals ranging from 30 to 90 years of age. 2. Simple confusion of ideas in senile individuals. Hallucinations are not present in this class, and dementia not rarely follows. 3. Delirium in alcoholism. In this class the delirium appears earlier and subsides more rapidly. 4. Confusion of ideas due to inanition, occurring in extremely marasmatic individuals and followed by death.

Delirium tremens develops not rarely after the removal of cataract, but, although it possesses many characteristics in common, it is so obviously different from that form of delirium which operates in the majority of cases which will be cited in this paper, that further mention of this class of patients will not be made, it being the purpose of the writer to consider only those cases which fall under the first category in Frankl-Hochwart's division.

Before giving the histories of the cases which the writer has to offer, he thinks it will be of interest to mention the different theories which have been held to account for the production of this delirium, so that in the report of each case the hearer may satisfy himself of the particular agency which seemed to be operating in each instance.

In looking over the literature of the subject, one is at once impressed with the diversity of opinions regarding the origin of the delirium, as it appears as though each author ascribed the agency which seemed to have the greatest influence in the production of the delirium in his own case as the causal factor in all cases of delirium.

As has been already stated, a number of authors, however, assume a special disposition towards mental derangement in all who become delirious following operations upon the eye. Among these may be mentioned Arlt, Schmidt-Rimpler,²² Knies,¹⁵ Warloment, Hirschberg,¹² and Valude. They believe that mental symptoms arise in only very weak and nervous people, but fail to mention further characteristics of this predisposition. Lopez thinks that the delirium occurs only in those who are already actually mentally alienated, although usually in a latent form, the mental weakness having passed unperceived by the physician.

Among occasional exciting causes may be mentioned Parinaud's²⁶ explanation of extreme preoccupation of the patient for several days preceding the operation itself, and secondly, the withdrawal of all external impressions during the first few days after the operation, resulting from the absolute rest in bed, and the darkness and seclusion enforced by the closed eyes. Schmidt-Rimpler²² is strongly of the impression that one of the chief factors in the production of the delir-

ium is the bandaging of both eyes, and in support of this theory cites two cases in which no operation was performed, but who developed delirium, as he thought, simply by reason of their being confined in a darkened room during the treatment for their ocular affection. One of these cases was that of a young man, 19 years old, who was suffering from iridochoroiditis; the other that of a man, 59 years old, who had plastic-iritis. This theory is supported by Sichel,³³ Swanzy,³⁵ Valude, Borelli,⁸ and Armaignac; the last three authors giving the notes of cases where the delirium disappeared with the removal of the bandage.

Another set of authors, including Galezowski,¹⁰ Salvador, and Angela Ledda, attributes the delirium to the action of atropin. Grandclement¹¹ subscribes to this theory also, as the mental condition of a case observed by him was made worse after each instillation of this drug.

While it is evident that in alcoholism the excitement consequent upon the operation, conjoined with the depressing circumstances which are attendant upon the after treatment, may easily provoke a delirium of persecution, it is not my purpose, as before mentioned, to consider this type of cases in this paper. I will, however, in this connection refer to a case reported by Lopez,¹⁹ when the delirium occurred in an alcoholic, in whom the eyes were not bandaged and where the wound healed perfectly. Lopez thinks that it is a circumstance worthy of consideration that he has always observed the delirium in the old and atheromatous, and says this has led him to think that this disease of the vascular system plays an important role in the production of cerebral troubles, and subsequently of maniacal paroxysms. He adds that it is not strange that the cause of the delirium in question should be charged by some to alcoholism, as this is a frequent factor in the production of atheromatous degeneration.

An additional theory is mentioned by Berger,² who says that he remembers that Meynert, of Vienna, ascribed the production of the delirium to the excision of part of the iris, which is one of the steps in the common operation for cataract. Berger, however, remarks that this theory is no longer tenable, since Parinaud has observed the delirium following the extraction of cataract without iridectomy.

The restriction in diet and lessening of the amount of food immediately before and after the operation has also been advanced as a cause. Dupuytren was the first advocate of this theory, for as early as 1832 this author found that after he gave his patients sufficient nourishment, mental derangements occurred much more rarely. Parinaud and Gillett de Grandement support this theory, for both think that the weakness induced by the restricted diet is an important factor in precipitating the delirium; the latter author citing a remarkable instance which was evidently induced by this cause.

Martin²⁴ also, who has contributed a recent and comprehensive article on the subject, holds that the delirium is due to inanition, but thinks that this is induced chiefly by the withdrawal of alcohol. He does not believe that the mental derangement in this class of cases is an alcoholic delirium in the sense that the subjects are ever intoxicated by alcohol, but that it is delirium occasioned by the privation of this agent in individuals who are accustomed to it in moderate amounts; for he thinks that the brain, especially in the old, which has been habituated to act normally under

the influence of alcoholic stimulation, becomes deranged if this agent is withdrawn.

Showing the tendency of modern medicine, Fromaget,⁶ writing quite recently, thinks the delirium is due to autoinfection as a result of uremia and toxins originating in the intestines, for he is of the opinion that these conditions are favored by the disturbances of the liver, kidneys and heart, which are common to the aged. In support of his views he gives the notes of a man aged 92 years, in whom an anuria prevailed two days after the removal of the lens, the flow of urine being increased after some difficulty by injections of caffeine.

I will now cite two cases of delirium which recently occurred in my own practice, and will then add the notes of a series of cases of a somewhat similar nature which were collected for me from the records of the past few years of the Wills Eye Hospital, by Dr. A. C. Snell, at that time a resident surgeon of that institution. The notes of two additional cases, kindly proffered by Dr. C. A. Oliver, are also appended.

CASE 1 was that of a man, aged 78 years, who had had failing sight in his right eye for 6 years, while deterioration in vision in his left eye had been noticed but two years previously. Notwithstanding his advanced age, his health was excellent, his disposition extremely cheerful, and his mind remarkably well balanced. He was a man of education and was most anxious to have his sight restored to him so that he might read again. His habits were temperate, as he drank but rarely. Examination showed that the reduction in vision in the right eye was due to a cataract which was almost mature, while the lens in the fellow eye, although cataractous, was still sufficiently transparent to permit of a distinct view of the fundus.

As the vision in his best eye was so poor that he could no longer get about without considerable difficulty, I determined to remove the lens from the right eye. This was successfully accomplished shortly afterwards by the combined method, with the assistance of Dr. Wm. Zentmayer, cocaine being the anesthetic employed. Before applying the bandage to both eyes, as is the custom of the author, 2 drops of a 4-grains-to-the-ounce solution of atropin were instilled into the operated eye. The patient was seen later in the evening of the same day, and as he complained of pain over the scapulae caused by the constrained posture of lying flat on his back, several pillows were placed under his shoulders and he was raised into a recumbent position. Otherwise he seemed quite comfortable. His urine was voided without difficulty upon several occasions, and he received milk and beef-tea every few hours. At the visit the following morning the author learned that the patient had had a restless night on account of the pain in his shoulders, but his pulse was regular and his temperature was normal, and his mind seemed unaffected. The eye was redressed and found to be in a satisfactory condition, so that the bandages were re-applied after 2 drops of atropin had been instilled. A few hours after this I was suddenly seized with influenza and was compelled to relinquish the care of the case to Dr. Zentmayer. From him it was learned that upon the following day, the third day after the operation, the patient became violently delirious and was restrained from acts of violence with the greatest difficulty, the services of a powerful male attendant being constantly demanded to keep him in bed. His bowels were opened with croton oil, and chloral and bromids were administered in large doses, and the bandage was removed from the unoperated eye. After 3 days of this active medication the delirium subsided and the patient returned to his normal mental condition. The eye did extremely well, and when seen a week later, notwithstanding the irritation to which it must have been subjected while the patient was so violently delirious, it was almost entirely free from inflammation. The blood from the iridectomy was almost entirely absorbed, and the corneal incision was firmly and evenly healed. Six weeks later the proper correcting glasses were prescribed and full visual acuity attained.

With the exception of the 3 days of delirium, the

patient was perfectly rational, and though I have seen him many times during the past six years, I have never noticed the slightest tendency towards mental aberration. Indeed, his mind is wonderfully bright and he often says that he thinks himself quite capable of filling the difficult and responsible position of which he was the incumbent in his younger days.

CASE 2.—This patient, a large, hale man 82 years of age, had noticed that the vision in the left eye had been failing for 5 or 6 years past that of the right eye but 2 years. The examination revealing a cataract which was quite mature upon his left eye, and the vision in his right eye being reduced to $\frac{1}{5}$, his consent was gained to the removal of the lens in the left eye. He was accordingly admitted to the Howard Hospital and the combined extraction performed under cocaine. The removal of the lens was accomplished with some difficulty, as it was found necessary to have recourse to the loop, as the lens glided under the upper flap when the attempt was made to express it by pressure and counter-pressure with the curets. After the toilet of the eye had been completed, 2 drops of a 4-grains-to-the-ounce solution of atropin were instilled and both eyes were bandaged. The behavior of the patient during the operation had been most exemplary, and he assisted me greatly by his perfect control of his eyes, not allowing them to wander while the instruments were in contact with the globe. When seen by me at the end of 24 hours, the patient was resting quietly and seemed fully contented with his surroundings. Another man had been operated upon for cataract on the same day, and the two old men in adjoining beds chatted quietly and pleasantly with one another to while away the time and to lighten the constraint of their positions. At the end of the second day, however, towards evening, the patient said that he would remain quiet in bed no longer and insisted upon rising. The delirium soon became very marked, he thought that he was being persecuted, that the nurses and resident physicians were trying to poison him, and he demanded a knife to defend himself from his tormentors. His temperature, which had been slightly subnormal increased a degree and remained so for 24 hours. His pulse also was accelerated. His urine was voided in a normal manner and was not diminished in quantity, nor of a higher specific gravity than prior to the operation. Although watched with the greatest care and although his hands were placed in a muff to avoid such an accident, upon one occasion he managed to get his hands loose and tore the dressing off the eyes. He was very violent for three days, and would undoubtedly have taken his own life had an opportunity offered itself. Chloral and bromids were administered in high doses and his bowels opened with several compound cathartic pills. The delirium disappeared on the third day almost as suddenly as it appeared, and he has never shown any mental aberration since.

His family being questioned regarding his mental condition prior to the operation, it was ascertained that he had never manifested any disposition towards insanity previously, but that on the contrary they had considered him a most remarkable man for his years. I have talked with him a number of times since the operation, and have found him intelligent and cheerful and quite perplexed himself as to how to account for his mental aberration following the operation. Notwithstanding that the eye was much injected for a time after the dressings were torn off, he made an excellent though prolonged recovery. Glasses were prescribed about 3 months after the operation, which gave him a $\frac{2}{3}$ vision and the ability to read the finest type.

WILLS EYE HOSPITAL CASES.

CASE 1.—F. P. C., aged 65 years. Service of Dr. Jackson. Simple extraction. Delirium appeared on the third day after the operation and was controlled by hyoscin in a few days. Both eyes had been bandaged, but no mydriatic was employed. No known disposition towards insanity. Eye made a good recovery.

CASE 2.—J. S. K., aged 81 years. Service of the late Dr.

Keyser. Simple extraction. Hallucinations appeared on the second day after the operation. Both eyes bandaged and no mydriatic instilled. Delirium passed away in a few days, leaving patient in his normal mental condition, which was said to be excellent.

CASE 3.—F. K., aged 79 years. Service of the late Dr. Keyser. Simple extraction. Both eyes bandaged. On the day following the operation, atropin was instilled into the operated eye and the bandage replaced upon that eye, but removed from the fellow eye. Upon the evening of the following day the patient became very delirious and restless; this condition persisting for over a week. No mention is made of any mental peculiarity before the operation or after the delirium subsided.

CASE 4.—G. T. R., aged 76 years. Service of Dr. Jackson. Simple extraction. Delirium set in on the third day after the operation. Both eyes had been bandaged but no atropin employed. Bandage removed from the unoperated eye as soon as the delirium manifested itself, but this continued a week despite active treatment with chloral and bromids. Although the wound did not close until 4 days after the operation, the eye made a good recovery.

CASE 5.—R. R., aged 66 years. Service of the late Dr. Keyser. Simple extraction. Talkative delirium appeared 24 hours after the operation. Bandages removed from the unoperated eye and patient allowed out of bed; delirium still persisted, becoming more violent; patient manifesting a desire to jump out of the window. Mental aberration persisted 6 days. No atropin employed. Eye made good recovery. No disposition towards mental aberration.

CASE 6.—Mrs. H., aged 65 years. Service of Dr. Fisher. Simple extraction. Delirium on the second day after the extraction, being converted into actual acute mania by the end of the third day. Both eyes had been bandaged, but the dressing was removed from the unoperated eye and the patient allowed out of bed at the commencement of the delirium. The eye made a good recovery.

CASE 7.—Catharine V. M., aged 76 years. Service of Dr. Norris. Simple extraction. Large prolapse of vitreous followed the extraction of the lens. The day after the operation patient became restless and by evening was decidedly delirious, but was quieted by chloral and bromids. Administration of the hypnotics was continued for several days after the operation as the delirium showed a disposition to return towards evening. There was no family history of insanity or nervousness, but the patient was of a rather querulous disposition and seemed anxious on admission. The eye made a good recovery.

CASE 8.—Ellen McC., aged 65 years. Service of Dr. Norris. Simple extraction. Operation smooth, save for presentation of a small bead of vitreous after delivery of the lens. Atropin instilled. Forty-eight hours after the operation, patient became very restless and complained of being confined to the bed, and in a few hours a violent delirium manifested itself. The bandage was removed from the unoperated eye, and bromids and chloral were administered in high doses. The eye made a good recovery and the patient was discharged at the end of a week, although her mind had not yet fully recovered its normal balance. This patient was noted as being mentally deficient upon admission, as evidenced by hebetude and inattention to what was happening about her.

CASE 9.—J. E., aged 76 years. Service of Dr. Harlan. Simple extraction. Operation smooth. Iris prolapsed with the withdrawal of the knife, but was promptly replaced by gentle manipulation; some cortex remained; 24 hours after the operation the wound had not yet closed, though the eye was but little injected. The patient was exceedingly restless, talked somewhat incoherently, but seemed rational when addressed. He was placed on bromids and chloral, but despite these drugs became violently delirious on the following day, complaining that he was being poisoned and foully retrained in a strange place. The delirium was not talkative, but the patient was very obstinate and morose. Atropin was used at the time of the operation only. On the fourth day the patient became quite rational, and the hypnotics were withdrawn. The eye made a good recovery. The patient had always been a strong man in excellent health and had never manifested any previous tendency towards mental alienation, nor was there any history of nervous trouble in his family.

CASE 10.—Mrs. X., aged 62 years. Kindness of Dr. Oliver.

Simple extraction. Hypermature lens. Removed without difficulty, the corneal wound healing on the third day. Upon the morning of the third day the patient became maniacal and tried to tear the dressings from her eye. She was somewhat quieted by the hypodermatic use of hyoscin. During the night of the same day, she endeavored to take her life by jumping out of the window, but was prevented by the prompt assistance of an attendant. Subsequently she tried to smother herself in a small closet. In spite of these circumstances, which later were unceasingly guarded against, the eye made an excellent recovery. It was afterwards learned from her family that years previously she had had recurrent attacks of mania.

CASE 11.—M. B., aged 70 years. Service of the late Dr. Keyser. Combined operation. The delirium appeared a few hours after the operation, and lasted for 48 hours. The operation was successful and the eye made an excellent recovery. Both eyes were bandaged throughout the delirium, and atropin was instilled daily into the operated eye.

CASE 12.—S. S., aged 70 years. Service of Dr. Berens. Combined extraction. Patient became restless on the second day after the operation, and 24 hours later violent delirium supervened. Both eyes were bandaged until the end of the second day, when the bandage was removed from the unoperated eye. Atropin was instilled at the time of operation, and twice daily until the patient was discharged 2 weeks later with an excellent result. The delirium in this case was controlled by trona.

CASE 13.—H. H., aged 51. Service of Dr. Croskey. Combined extraction. Delirium appeared upon the fourth day after the operation, associated with great depression of spirits and general weakness. The mental symptoms persisted 4 days, but were relieved by the enucleation of the globe, which was necessitated at that time on account of panophthalmitis. The cataract was of the complicated variety and a scoop was used in its delivery, necessitating the loss of considerable vitreous.

CASE 14.—A. P., aged 67. Service of Dr. Fisher. Combined extraction. Restlessness and delirium on the second day after the operation, quieted by $\frac{1}{4}$ grain of morphia sulfate. Both eyes bandaged at time of delirium, but atropin not used until later. Patient healthy but rather dull and childlike. Eye made a good recovery. Nine months later a combined extraction was performed upon the fellow eye. Delirium manifested itself 2 weeks after this operation, but was successfully combated by chloral and bromids. Both eyes had been bandaged, and atropin had been used at the operation.

CASE 15.—G. H., aged 60 years. Service of Dr. Berens. Combined extraction. Wound closed 24 hours after the operation, without undue reaction. Violent delirium on the third day after the operation; patient fancying the room on fire, and calling out murder. Delirium was controlled in 4 days with chloral and bromids. Both eyes were bandaged until the third day, when the dressing was removed from the unoperated eye. Atropin was not employed until after the delirium had manifested itself. Patient was a strong, healthy man, perfectly self-contained and docile, and of good habits.

CASE 16.—Samuel S., aged 80. Service of the late Dr. Keyser. Combined extraction. Small iridectomy; lens delivered with difficulty, considerable cortex remaining; no atropin. Evidences of delirium manifested themselves on the evening of the day of operation. Chloral and bromids administered. Upon the following morning patient was quite delirious, complaining that he was unjustly detained and cruelly treated. This mental unrest continued for five days, requiring the constant administration of hypnotics to restrain him. The eye was finally lost from panophthalmitis.

CASE 17.—Adam S., aged 73. Service of Dr. Berens. Combined extraction. Operation smooth; slight hemorrhage followed the iridectomy; no atropin instilled. Third day after the operation, eye was quiet, but the anterior chamber was not entirely reestablished. The patient complained of troubled dreams the night previous, and within a few hours, despite large doses of bromid and chloral, became wildly delirious, screaming that he was being robbed and made frantic efforts to get out of bed. This state of mental excitement subsided after 4 days, but recurred after the needling operation for the cure of secondary cataract, which was performed

2 weeks after the primary operation. The patient was in excellent health prior to admission, had never been a drinker and was not what could be called a nervous man.

CASE 18.—John B., aged 66. Service of Dr. Fisher. Iridectomy for glaucoma. Delirium manifested itself on the second day after the operation; mild for several days, becoming violent on the fifth day. Patient thought that he had been locked in a cell, and wondered how he had escaped. Tried to jump out of the window and was controlled with great difficulty. Discharged from the hospital at the end of 9 days, as his mental condition was excellent and the eye was in a satisfactory condition.

CASE 19.—Robert McC., aged 60 years. Service of Dr. Jackson. Iridectomy for glaucoma. Operation performed under cocaine-anesthesia. Complicated by a profuse intra-ocular hemorrhage. The patient was placed in an upright position for 2 hours after the operation. Upon the following day the wound had closed and the eye was doing well. On the third day patient became exceedingly restless, and accidentally struck the operated eye with his hand, opening the anterior chamber. On the fourth day, whilst still delirious, patient evaded the nurse and jumped out of the second story window of the hospital, fracturing the middle third of the thigh. As the eye made a fair recovery, he was removed to the Pennsylvania Hospital for proper treatment of his broken leg at the end of a week.

CASE 20.—Mrs. X., aged 56 years. Kindness of Dr. Oliver. Iridectomy for glaucoma. The patient, who possessed good personal and family antecedents, had a double subacute attack of glaucoma, necessitating the immediate performance of a double iridectomy, the operation being successfully accomplished at one sitting without the employment of any general anesthetic. The dressings were removed the next day and the patient was given her full liberty within 72 hours' time. A mild wandering delirium that lasted for more than a month's time appeared, 24 hours later, and as suddenly ceased without the use of any medication. The patient subsequently enjoyed the best of health and has remained entirely free from any apparent form of mental aberration up to the present time—some six years after the operation.

CASE 21.—Al. S. Service of Dr. Berens. Foreign body in eye. Three hours prior to admission into the hospital, the patient had been struck in the left eye with a piece of steel, inflicting a penetrating wound which embraced the center of cornea, and implicated the iris and lens, the lens being densely cataractous and the iris prolapsed into the corneal wound. The patient was etherized and the iris was freed from its attachment by a double iridectomy, and a quantity of lens-matter removed by the curet. A magnet was then introduced through the point of entrance of the foreign body, and carried back into the vitreous in the direction the fragment was supposed to have taken, and upon the withdrawal of the instrument the chipping was found to be adherent to it. On the fifth day after the accident, the pain, which had been very great, the result of an iridocyclitis which had been set up in the eye, became so severe that the patient became delirious and highly excited. The eyes had not been bandaged after the operation, although atropin had been used freely during the entire treatment. The delirium was very marked for 2 days, but subsided very rapidly after the removal of the globe on account of panophthalmitis. Although never insane, this patient might have been designated as nervous, for he worried constantly about his family and himself. He was non-alcoholic, of an excellent disposition and industrious. His mental symptoms were supposed by Dr. Berens to have been induced by the great pain provoked by the iridocyclitis, for, as before mentioned, as soon as the eye was removed and the pain relieved, the delirium subsided.

CASE 22.—Harry P., aged 15. Service of Dr. Berens. This lad inherited a tendency to be nervous from his father, who was of an excitable and irritable nature. His mother, on the other hand, was collected and calm. When but 3 years old he had St. Vitus' dance following an attack of grip, with a recurrence of the same affection some years later as a sequel of whooping-cough. His sleep was always more or less disturbed, as he would toss about and frequently call out. The day before the accident on account of which the patient was admitted to the hospital, he became much excited in assisting in the recovery of the body of a comrade

who was drowned whilst swimming. The injury to his eye was the result of an explosion of a can of powder, as a result of which the globe was perforated in the ciliary region to the nasal side, and the conjunctiva, sclera, and cornea badly burned by the powder. The iris was prolapsed into the wound, but the lens was apparently uninjured. The prolapse was snipped off, as much of the powder picked out of the eye as was possible, and ice compresses, atropin, and boric acid applied to the eye. The day following admission he became wildly delirious, muttered incoherently and kept striking at imaginary objects. Notwithstanding the frequent administration of morphia, chloral, and bromids, the delirium continued for five days. The eye recovered its vision with the formation of a ciliary staphyloma.

Summary.—To briefly summarize the cases, it will appear from the foregoing that of these 24 cases, the delirium appeared 11 times after simple extraction; 8 times after the combined operation; 3 times after iridectomy for glaucoma, and twice in traumatic cases. Three of these cases were in subjects over 80 years of age; 7 over 70 years; 9 over 60 years, and 2 during the sixth decade. The traumatic subjects were much younger.

The delirium appeared during the first 24 hours after the operation in 2 instances; on the second day in 8; on the third day in 6; and on the fourth in 2 instances. No atropin was used in 6 instances; in 4 others it was not employed until the delirium had manifested itself, and in the remaining instances this drug was instilled at the time of the operation. Its employment did not seem to have any influence whatsoever upon the mental condition. Both eyes were bandaged after the operation in every instance, but the dressing was removed from the unoperated eye in 9 instances, as soon as the delirium manifested itself, without giving any appreciable relief to the mental condition.

It was specifically noted in 9 cases that there was absolutely no tendency towards mental derangement; there being evidence of such a condition previously in but 2 instances, other than in the traumatic cases, where there was strong evidence of previous mental disease. All of the eyes made a good recovery except in 2 cases, enucleation being demanded in one of these on account of panophthalmitis, and in the other on account of traumatic iridocyclitis.

The delirium was of the same character in all, beginning with a mild restlessness which rapidly developed into an active delirium with hallucinations and ideas of persecution, but passing rapidly under control by the proper administration of narcotics; permanent affection of the brain being remarked in not a single instance.

As regards the frequency with which the mental derangements occur, it may be noted that the 16 instances collected from the Wills Eye Hospital records extended over a period of four years, during which time 770 cataract extractions had been performed in that institution. This complication, however, undoubtedly is present in a much higher proportion of cases than this, these low figures being readily accounted for by the fact that it is the custom of the resident surgeon to administer hypnotics at the first manifestation of mental unrest, and only cases in which this is not sufficient to quiet the patients, and in whom actual delirium arises, are tabulated.

With the facts contained in this brief summary at hand, the refutation of many of the theories which have been mentioned above is a simple matter. Thus, the assertion that the mental aberration is due to a predisposition to mental unsoundness is shown to be without

any foundation whatsoever, for with but three exceptions all the cases which have been collected in this paper possessed a healthy mentality. The permanent recovery of mind in each instance after but a few days or a week of delirium is a further indication of the accidental and transient character of the delirium. Moreover, it has been the writer's experience that operations upon the eyes of those who are predisposed to insanity, instead of precipitating an attack of delirium, have in several instances markedly benefited the mental condition; indeed, in two cases of blindness due to cataracts in insane subjects he has had the happy experience of seeing restoration of the mental faculties attend the removal of the opaque lenses.

Martin²⁴ could satisfy himself of a state of mental weakness prior to the operation in but 2 cases mentioned in the literature, *i. e.*, that of Warloment, where the statement is made that his case seemed mentally "innocent," but that he had never given an other sign of delirium or insanity; and that of Hirschberg's, where the patient was said to have some mental unsoundness. He says that in none of the 20 or more other cases mentioned is there any reason to suspect a prior predisposition towards insanity. Lopez's claims of a mental predisposition should not be regarded, as two of his cases were probably quite insane before the operation, and should not really have been described as instances of postoperative psychoses; one of the cases occurring in a family of eccentric members and the patient remaining insane for two months after the operation, while the second case was melancholic.

Sweet's²⁵ case belongs to the same category. This author cites an instance of delirium of persecution following a cataract extraction which was evidently excited by the fear of going blind. The patient was very nervous, and although there was no former history of insanity, there was probably a strong disposition toward mental weakness. The patient died two months after the operation.

In opposition to the bandage theory is the fact that even after it is removed from the unoperated eye, there is usually no improvement in the mental condition. Thus, neither in Warloment's and Hirschberg's¹³ cases nor in any of those cited by the writer was there any improvement after the bandages were removed. Gorcecki, also, and Calderon⁹ saw delirium after cataract operation in nonalcoholics, when the eyes were not bandaged, and the same was true in case 14 of the present series.

This would seem to be in exact contradiction to a case reported by Valude, for, in this instance, as soon as the bandage was removed from a 75-year-old patient who had developed delirium as a result of double iridectomy for glaucoma, the delirium ceased; and likewise a case of Borelli, where amelioration was almost immediate when coquilles were substituted for the bandage. Martin, however, disposes of both of these objections, or rather exceptions, as follows: Valude's case was a simple coincidence, *i. e.*, the bandage being removed about the time that the other remedies which had been employed became efficacious, while Borelli's case was not one of true delirium, but simply one of a fixed idea which existed before the operation.

It can also be argued against the bandage and exclusion of light theory, that if the delirium be due to this cause, insanity should be much more common among the blind than is actually the case.

The statistics of the summary show conclusively that

atropin, also, could not be considered as a causal factor in the production of the delirium. Cocain can also be eliminated. Indeed it would seem to be proven beyond question that the condition of the eye itself has nothing to do with the development of the mental alienation.

But three theories remain—that of excessive preoccupation upon the part of the patient prior to the operation, that of the withdrawal of food, and that of autointoxication. Of these, the latter two may be readily disposed of, at least in so far as the cases which came under my observation are concerned, for I think that there can be no question of starvation in any of the cases which I have reported, as in my private practice it is my custom to make no change in the diet until 24 hours before operating. At this time the first preparations are made for the operation; the patient is bathed and the eye which is to be operated upon is protected by an antiseptic dressing after thorough flushing with the boracic-acid lotion. A light supper is then administered, which is followed by a laxative pill at bedtime. The following morning the patient partakes of a simple breakfast, and as the usual hour of operation is in the afternoon, a glass of milk and a cracker are given at luncheon. After the operation milk is again repeated at frequent intervals, if thirst be complained of. The diet of the second 24 hours also is largely a milk one, though broths or beef tea are given twice to prevent extreme constipation. On the third day the patient is usually gotten up out of bed and placed on a soft diet, and if the bowels have not been opened, a laxative pill administered. On the fourth day liberal and supportive meals are prescribed. I follow this general plan in my own practice and think that this is the course usually pursued by the majority of eye-surgeons. I believe, therefore, that the theory of insufficient nourishment is not tenable.

Similarly I do not think that the recent theory of autointoxication which has been advanced by Fromaget⁶ could have operated in any of the cases which I have cited, for care is always exercised in the institutions with which I am connected to avoid any such complications. Thus it is a rule of the Wills Eye Hospital that the urine of every cataract patient shall be examined the morning of the day of the operation, and the resident surgeons are particularly instructed to inquire concerning retention after operation. These precautions were adopted in all of the cases which I have reported, and retention of urine can be eliminated in all. The bowels also, if nature has not already accomplished this, are invariably opened on the third day by a cathartic, so that there could be no autointoxication from this source.

After a critical study of the entire subject I have finally reached the opinion that the cause of the delirium after operation upon the eyes is largely psychic, and I agree with Parinaud that it is due to the preoccupation upon the part of the patients prior to and after the operation. While they may appear calm and collected and submit to the operation most cheerfully, if one takes the trouble to scrutinize them closely, in most instances he will find that this state of quietude is assumed and that in reality there is a great though suppressed excitement.

The very thought of sight after the weeks and months, nay, unfortunately, in many instances, after the years of blindness, is enough to upset their mental equilibrium, and the desire to assist the operator dur-

ing the operation, and not to wince at any pain or to do anything that might mar its success, must also be a great tax on their courage, and calls forth all of their power of self-control; and then, following the removal of the lens, the glimpse, though momentary, which is obtained of the outside world, which has been so long hidden from their gaze, and the realization that the suspense is over, must undoubtedly occasion more or less psychical disturbance.

Undoubtedly also, the constraint of the supine position and the unusual stillness of the surroundings favor still further the temporary change in the psychic balance.

What the other factors are, which in addition to the preoccupation determine the delirium, are as yet unknown. The frequency with which the delirium is encountered should, however, be recognized, and proper treatment be administered at the first indication of its appearance. This undoubtedly consists in the free and repeated administration of chloral and bromids. As the statistics do not show any marked improvement in the symptoms to follow the removal of the bandage from the unoperated eye, this step is not to be advised, unless the wound caused by the operation be thoroughly healed. There is also no reason to discontinue the employment of atropin.

Constant oversight and judicious and tactful nursing is most essential, and amelioration in the mental condition frequently follows the installation of a proper person by the bedside.

It is proper to mention in this connection a communication which has been made by Dukes⁶ to the effect that the restlessness of old people is due to the gradual age-failing of the scavenger organs, and that it is owing to their incompetence that the blood is not sufficiently depurated and arterial tension increased. He believes that the remedies best adapted to calm these individuals are those which relieve the arterial tension, such as nitroglycerin, though he found erythrol tetranitrate in doses of $\frac{1}{2}$ to 1 grain to be even more valuable.

RESOLUTION AS AN ETIOLOGICAL FACTOR IN POST-CRITICAL TEMPERATURE OF LOBAR PNEUMONIA IN CHILDREN.

By WILLIAM N. FISHER, M.D.,
of Washington, D. C.
Outdoor Physician to the Children's Hospital.

LOBAR or croupous pneumonia, a condition which in children has become so familiar to all, whose turning point for the better is one of the most beautiful phenomena of a self-limited disease, ending as it does by crisis, usually between the fifth and eighth day, frequently gives rise to grave apprehensions when there occurs a rise in temperature which is sudden in its onset, rarely reaching higher than 103° F. and taking place at from 36 to 48 hours after the crisis is complete.

A synopsis of the histories in 4 cases which have these characteristics is given, with particular reference to temperature, pulse, and respiration.

CASE 1.—Katie S., female, white, aged 2 years. Family history: Mother is living, and is in good health. Father is also living. He has arteriolateral sclerosis. She has one brother and one sister who are in good health. There is no history of syphilis or tuberculosis. Previous history: Labor was normal; she was well formed at birth, and was breast-fed; dentition was normal; she was never sick before present illness. Present history: Forty-eight hours after the illness began, consolidation of the lower lobe of the right lung was well-marked. Perfect physical signs of lobar pneumonia existed. The temperature ran a high continuous course, varying between 104° F. and 105.4° F., pulse 132 to 160, respirations from 60 to 78 a minute. The crisis took place on the seventh day of the illness and had become complete on the eighth day. The temperature now remained normal for 48 hours, when it began to rise, and in 12 hours had reached 102.8° F. For the next 24 hours it varied between 102.8° F. and 103° F., when it began to drop, and in 24 hours had reached normal. The only variation in the temperature from this time on was that usually noted in children.

During the subnormal period the respirations ranged between 32 and 52 per minute, pulse between 80 and 90 per minute. During the postcritical rise in the temperature the respirations remained about the same in frequency, but improved very much in quality. The pulse ranged between 90 and 120 a minute. At the end of the secondary rise the respirations had become less frequent, ranging between 26 and 40 a minute. At the end of crisis no change could be made out in the character of the consolidation. During the subnormal stage of the temperature, rales redux made their appearance. Beginning with the secondary rise in temperature, rales became numerous, and the breathing became bronchovesicular in character. There was a marked improvement in the character of the breathing, and progressive improvement in the number of rales during this period. When the temperature had again reached normal, bronchovesicular breathing was beginning to give way to the normal vesicular murmur. Rales persisted 10 days after the crisis, when a physical examination failed to reveal any abnormal condition.

CASE 2.—James W., male, colored, aged 2½ years. Family history: Mother and father are living, in good health. He

has two sisters and one brother in good health. There is no history of syphilis or tuberculosis. Previous history: Labor was normal, he was well developed at birth and breast-fed; dentition was somewhat delayed. He had a mild attack of rachitis, the bony lesions of which are slightly visible. He has been subject to attacks of intestinal indigestion. Present history: The present illness is his first severe sickness. Consolidation was well marked 36 hours after the first symptoms made their appearance and affected the entire lower lobe of the left lung. Crisis took place on the fifth day. The temperature became normal in 8 hours.

During the febrile period prior to crisis, the temperature ranged between 104° F. and 105.5° F. For 36 hours subsequent to crisis the temperature was subnormal. It then began to rise, and in 12 hours registered 103° F. For 16 hours the temperature fluctuated between 101.8° and 103° F., then it began to fall. In 48 hours from this time the temperature was again normal. Normal fluctuations of the temperature were now noted throughout the convalescence. During the stage of consolidation the pulse ranged between 120 and 150 per minute. Respirations between 60 and 75 per minute. During the subnormal stage the pulse ranged between 45 and 60 per minute. During the postcritical rise the pulse ranged between 120 and 140 per minute, and the respirations between 32 and 45. Signs of resolution progressed nicely during this period, but not so rapidly as in the first case.

When the temperature had again reached normal there was still some bronchovesicular breathing heard. Rales had markedly decreased in number.

CASE 3.—Agnes W., female, white, aged 1 year. Family history: Mother is living, in good health. Father's history,

nil. No other children in family. Previous history: Labor was normal, she was well formed at birth, breast-fed, and has been a healthy baby. Present history: The child had been ill for five days when she came under observation with a history of having a high continuous temperature. The temperature when she was seen was 104° F. The physical examination revealed a consolidation of the lower lobe of the right lung, with a few moist rales. Pulse 104, respirations 68. In 12 hours crisis was complete. The temperature remained subnormal for 48 hours, when it began to rise, and in 21 hours the thermometer registered 102.8° F. In the next 4 hours it had gone up to 103° F. The temperature remained here only a short while when it began to fall and in 24 hours it had reached normal. No further rise was noted. During the subnormal stage the respirations ranged between 35 and 60, the pulse between 100 and 128 per minute. During the secondary rise of the temperature the respirations ranged between 40 and 60, the pulse between 120 and 150 per

minute. The pulse here became very weak, and stimulation was increased. The patient subsequently died from an attack of acute gastroenteritis.

CASE 4.—Maggie A. W., female, aged 3 years; no history obtainable. Physical examination revealed a consolidation of the lower lobe of the left lung, with a few moist rales. Temperature 104° F., pulse 116, respirations 43 per minute. Crisis was complete in 36 hours from the time when first seen. The temperature remained subnormal for 36 hours. It remained normal with very little change in the signs of consolidation for 56 hours, when there occurred a sudden rise in the temperature. The thermometer registered 100.5° F. In 24 hours the temperature was again normal. It was not until this postcritical rise in temperature took place that the breath-sounds changed from bronchial to bronchovesicular in character. There was a marked increase in the number of rales just prior to this rise in temperature.

The rales diminished considerably following the decline in temperature. The temperature in this case is not so well marked as in the preceding ones, but the result of the physical examination is practically the same. The respirations before crisis were 49 and the pulse 120 per minute.

After the crisis was complete the respirations ranged between 92 and 100 per minute. During the postcritical rise in temperature the respirations varied between 28 and 32 per minute, and the pulse between 98 and 100 per minute.

Three of the cases reported occurred during my term as resident physician at the Children's Hospital. I am indebted to the Hospital authorities for the use of the records.

The following table has been prepared to show the ratio existing between the pulse and the respiration. The subdivisions of the disease are arbitrarily arranged, and are based upon the character of the temperature as it is presented in these four cases:

Febrile stage. Pulse, Resp.	Subnormal stage. Pulse, Resp.	Postcritical stage. Pulse, Resp.
2.11 to 1	2.12 to 1	2.41 to 1
2.00 to 1	2.11 to 1	3.29 to 1
2.05 to 1	2.42 to 1	2.70 to 1
1.10 to 1	2.45 to 1	3.30 to 1

The chart is that presented by Case 3. A summary of the above cases shows the following points:

1. That a postcritical rise in temperature took place in all the cases, and that the temperature was somewhat uniform as to time, height, and duration.
2. That while the ratio existing between the respirations and the pulse during consolidation was reduced to an enormous extent, the ratio existing during the postcritical rise in temperature was increased.
3. That these conditions being true, there must have been some cause common to all.
4. That the rise in temperature bore a direct relation to the physical signs marking beginning resolution.
5. That the rapidity with which this secondary rise reached its highest point bore a direct relation to the extent of liquefaction.
6. That the rise in temperature was followed by an improved state of the affected area.
7. That as the condition in the affected area improved the temperature reached normal.

Holt, in his treatise on lobar pneumonia, states that a postcritical rise in temperature is due to one of two causes. First, extension of the disease to a new area. Second, the development of a pleurisy which is apt to become purulent. In the above cases in which a postcritical rise in temperature took place, neither an extension of the disease nor the development of a pleurisy

took place. The similarity in the rise of temperature would seem to add still another cause for such a condition.

To me it is a most interesting phenomenon, and one which seems to be fully explained in the light of recent investigations. I believe it to be a frequent occurrence. In some cases it is better marked than in others, but always sufficiently well marked to be correctly diagnosed should it occur.

The general characteristics of this elevation in temperature seem to be as follows: That from 24 to 48 hours after the crisis, there occurs a secondary rise whose ascent is rather rapid, the maximum intensity not reaching higher than 103° F., nor lower than 100° F. This temperature is accompanied by an increase in the ratio existing between the pulse and respirations. The temperature again reaches normal in from 36 to 48 hours. The only symptoms noted were those referable to the fever. In Case 2 no symptoms were noted.

Such rises in temperature quite frequently give no symptoms in children, and if it were not for the use of the clinical thermometer this postcritical temperature would, I think, escape observation in many instances. It not often happens that slight rises in temperature give rise to marked symptoms, and especially is this true in cases which have had their vital powers depressed by severe illnesses.

To find a patient with a temperature of 103° F. on the second or third day after crisis has taken place, with a weak, rapid heart, gives rise to serious considerations on the part of the physician. Especially is this so, if after careful examination of the chest and of the various systems no new lesion can be found to account for the condition.

In order to bring out the points which characterize this condition, it will be well to consider briefly the differential features with regard to new foci of infections and empyema. The rise in temperature being rather abrupt would lead one to think that a new area had been infected.

This form of pneumonia is well recognized, and is spoken of as migratory pneumonia. This condition is usually readily made out. The beginning signs of pneumonia may or may not be present on examination in portions of the lung known to have been previously free from the disease.

In new areas of infection the rise in temperature, if crisis has taken place, is usually very rapid. It reaches its former height or even higher within a short period. The physical signs marking the beginning consolidation will not always be found at first for the reason that a portion of the lung may become involved at a remote distance from the chest-wall. We have all seen cases, not secondary infections, but primary conditions, which did not show the slightest evidence of consolidation for from 36 to 72 hours after the attack had been developed.

When this secondary rise in temperature is due to the involvement of another lobe, there is a marked increase in the number of respirations, which not only increase to their former rapidity, but exceed it in proportion to the amount of pulmonary parenchyma thrown out of action. This rapid increase in the number of respirations, the marked diminution in the ratio existing between the pulse and the respirations, and the sudden rise in temperature, unaccompanied by the beginning signs of consolidation, taken in conjunction with the history of the case, is to me sufficient ground on which to base a diagnosis of reinfection.

The respirations are here the criterion. Too much importance cannot be given to this feature of pneumonia, namely, the ratio existing between the respirations and the pulse. Pleuritis may accompany this condition, and by its physical signs, give further evidence of the involvement of a new lobe. Delayed resolution is an extremely rare condition in children. If the dulness persists for more than 10 days there exists usually one of two conditions—delayed resolution, or empyema.

In the effusion following the pleuritis of lobar pneumonia in children, this condition is almost invariably purulent.

The leukocytosis which persists during lobar pneumonia subsides with resolution. In empyema the polymorphic nuclear leukocytes increase to an enormous extent. This is common, however, in all suppurative processes.

The rise in temperature in this condition may make its appearance at any time following the disease.

The temperature is generally septic in type, and continues until relief is given. The temperature in unresolved pneumonia partakes of this type. Unresolved pneumonia can usually be diagnosed quite readily from empyema. If the dull percussion-note be due to an unresolved pneumonia, bronchial breathing will be well marked. If the dulness be due to empyema it is accompanied by weak breath-sounds in a large majority of cases. When the empyema is great enough to cause decided pressure of the lung, transmitted sounds will usually be heard. These can be diagnosed by being heard in an intensified state on the unaffected side. The ratio existing between the pulse and the respiration in unresolved lobar pneumonia is little affected. If the temperature following pneumonia in these complicated cases can not be accounted for by well-marked evidences of an unresolved lobe, the second cause for postcritical rises of temperature, spoken of by Holt, should be strongly suspected. After from four to six days, should the temperature become of an irregular type, it is a wise procedure to examine the blood for the presence of a leukocytosis. If this condition exists, and has coupled with it dulness, which may have increased in extent, with the presence of weak breath-sounds, the pleural cavity should be aspirated. I consider the presence of breath-sounds in empyema of the greatest importance, and should never be sufficient cause for withholding the only positive means of diagnosis—namely, aspiration. In two cases which I recall, both cases ending fatally, breath-sounds were heard up to cessation of respiration over the side affected.

The sounds were transmitted in these two cases.

The postcritical temperature reported in the above cases seems to be fully explained from a pathological standpoint. Schmitzer and Ewald, working in Albert's clinic in Vienna, have recently studied anew the fever-producing chemical bodies indisputably set free in subcutaneous hemorrhages. While asserting that the older notion of the chemistry of fibrin-ferment cannot be entirely regarded as the fever-producing elements in the blood, they endeavored to isolate from such blood those chemical bodies which produce the symptoms of aseptic-wound fever. They claimed to have found two series of compounds exactly meeting this requirement, the nucleins and albumoses; both of these substances when injected into the bodies of healthy animals brought about febrile reaction. These bodies must have existed in the degenerated blood experimented on, and

were the result of degenerative processes in the albuminous constituents, and not due to the formation of fibrin.

The cases reported showed no condition, either in the lung or in any other system, other than the signs of resolution, to account for such uniformity in the temperature.

Beginning with or shortly following crisis, liquefaction of the alveolar contents begins. It consists of a fatty and granular degeneration of the red blood-corpuscles, fibrin, and polymorphic nuclear leukocytes. This liquefaction progresses more rapidly in some than in other cases.

During liquefaction nucleins and albumoses, together with fat and pent-up toxins, are set free.

The lymphatics now begin to functionate, and depending on the extent of liquefaction these fever-producing bodies are rapidly thrown into the system. The reaction is marked in proportion to the rapidity and the amount of absorption, plus excretion. The kidneys are always the site of more or less cloudy swelling. It is the cells which take such an active part in the excretion of solids that have undergone this change. The swelling of the organ interferes with the proper circulation of its blood.

These two causes, namely, loss of function by the cell concerned in excretion, and interference with the proper circulation, can lead to but one conclusion—crippled excretion.

The temperature rapidly rises and the pulse becomes accelerated. The pulse becomes weak and rapid, depending on the power of the system to withstand this new invasion.

Few or no symptoms may accompany the condition.

In the above cases the system seemed to rapidly become used to these products. The variation in the time of this postcritical rise of temperature seemed to depend on established resolution, while the height to which the temperature rose, and the constitutional symptoms produced would appear to depend on three causes: First, the rapidity of absorption by the lymphatics; second, by the lessened excretory function of the kidney; and, third, by the resistance offered by the system. Here again the pulse and respiration play a most important role in the diagnosis.

The ratio in each case existing between the pulse and respiration was increased. In conclusion, I wish to say that I believe this secondary rise to be a frequent one, depending on the absorption of a degenerated albuminoid mass containing fever-producing bodies. It is a condition which can be diagnosed, the diagnosis of which gives a great deal of satisfaction, and allays much uneasiness, not only to the physician, but to anxious parents and friends.

INVERSION OF UTERUS; UTERINE INERTIA; SHORT CORD.

By EDWARD K. BACON, M.D.

Lecturer on Surgical Anatomy, Michigan College of Medicine and Surgery,
Detroit, Mich.

MEDICAL art began with specialties, which later combined in generalities. Ancient things were reproduced and improved. New things are nearly all old. From the beginning of the human family, babes have been born and died; were born and grew into adult life. The study of the pregnant woman and her accouch-

ment has for ages been interesting. From the day the ovum and spermatozoon become enveloped in the folds of the uterine mucous membrane and the barrier disappears that separates them, they combine to become a new life. The peculiar disturbance the new life gives to the physiology of woman is wonderful. Physicians entering the lying-in-room know not but that before they retire, one life and perhaps two or more may pass into eternity. Conditions often arise rendering the birth-chamber a dread. Head and breech presentations we have all observed; with arm, shoulder, and back presentations many are familiar; complete uterine inertia, inversion, and short cord have been seen by a few.

The literature on some of these conditions is ancient. From the day of Hippocrates to the present day, books written on diseases of women and obstetrics devote pages to presentations and troubles following confinements. The ancients often observed displacements of various kinds, but I can find no record of their describing inversions. Many authors of the present day never saw a complete inversion. No ancient medical literature describes inversion. Hippocrates, Paulus of Aegineta, Aretius, Galen, Celsus, Morgagni, the translators Rhazes, and Albuscas, Arteus, Scultitius, Pari, and others of their days, described and treated prolapses, but none of them, as far as I have been able to find, knew of inversion, although it may have been observed without distinguishing it. Probably inversion has occurred at times since prehistoric woman's day. I believe it is not a trouble peculiar to civilization. In the latter part of the eighteenth century, and during this century, cases of inversion are recorded. Nearly all medical journals, since the days of John Hunter, have at times recorded cases of inversion. I have never found a satisfactory pathologic explanation of this mishap.

The uterus at the full term of fetal life weighs nearly as many pounds as the unimpregnated uterus weighs ounces. Eight ligaments aid in holding it in its normal position, and 3 pelvic muscles and 2 fascias complete the foundation upon which it rests. Vigorously acting uterine muscles keep its form from collapsing.

The ligaments of the uterus do not increase in strength nor size, with the exception of the round ligaments, which develop their muscle-fibers during the ascent of the impregnated uterus as the uterus increases in size during fetal life. The broad and lateral ligaments are carried up with uterine ascent. The sacro-uterine ligaments are not disturbed; the round ligaments are stretched, and near the time of quickening contract their muscle-fibers, aiding in the descent of the uterus. The folds of the peritoneum have but little resisting powers in holding the uterus. Relaxed uterine muscle-fibers, depleted uterine bloodvessels, enervated pelvic muscles, sometimes allow a heavy uterus to invert.

In the *American Gynecological and Obstetrical Journal*, October, 1899, Dr. W. M. Donalds, of Detroit, gave an interesting experience in the treatment of partial inversion, the variety most commonly seen. Dr. Burton Parker, surgeon to Emergency Hospital at Detroit, reports a case this month, that of a miscarriage, with hemorrhage and partial inversion, which he reduced with a sterilized end of a leadpencil.

Inversion may begin at the os and evert the uterus, continuing the eversion to a complete inversion. It may begin at the fundus, which inverts partially

through the os, or the uterus may completely invert. Cases of inversion produced by traction on the cord begin as an eversion, that is, the uterus rolls its mucous surfaces out, beginning at the os, until the whole is inverted. Inversion following forceps-delivery begins as an eversion, starting at the os. Ambroise Paré gave the history of a case he called prolapsus uteri, in which he ligated the uterus into equal parts at its neck, taking it away in a few days, after sloughing at the point of constriction. Surgeons previous to his day did the same. It may be possible that in those cases, instead of operating on a case of prolapse, they removed an inverted uterus.

I believe hemorrhage is a great factor in producing inversion; this produces weakening of the muscular structures which support the womb. Loss of blood must weaken nerve-centers that control those muscles; hence not only weaken the muscular cells because of lack of proper blood-supply, but weaken the nerve-supplies, enervating their muscular structures, and lessening the power to hold up the heavy uterus. Traction applied to the child or placenta in such a uterus will cause it to invert. That hemorrhage may occur without inversion certainly weakens the theory, but I believe that excessive bleeding from the uterus is a prominent factor. The same condition allows the fundus to invert, because of its weight.

May 10, 1896, I was called to attend Mrs. D., aged 32, a primipara, living in the third story of a tenement block in Detroit, in the eighth month of a twin pregnancy. For a year her husband, her child, and herself, had lived in two rooms. The surroundings were unhygienic. When I arrived she was suffering with labor-pains, the os being dilated to the size of a quarter-dollar. She had some hemorrhage. Being placed into bed and sedatives given, I tried to stop the uterine contractions. The vagina was lightly packed with gauze, but in a few hours labor pains began at regular intervals. The first child was born feet first, and alive, but died in a few hours. The second child was born 20 minutes later, and lived 12 hours. The placentas were united, each side having a separate cord. The uterus contracted sluggishly. A hot saline douche was given and the toilet completed with sterile napkins. Ergot was administered, and in a few hours the uterus was contracted, but not firmly. She was resting easily when I retired at 4 p.m. At 10 p.m. the pulse, temperature, and respiration were normal. The bowels and bladder had been evacuated. She had no after-pain, but some hemorrhage had occurred. She was given another saline douche and dressed as before. Examination of the uterus showed it relaxed with a tendency to bleed. Ergot and quinin were given twice during the next 8 hours. The following morning she was feeling well, but there was some slight hemorrhage. The napkins were changed but no douche was given. She was placed on a light diet. The next day, with the exception of a relaxed condition of the uterus, she was doing nicely. The napkins were changed and a douche of hot saline water was given. The light diet was continued and ergot was given in ten-drop doses every three hours. The fourth day quite a hemorrhage had occurred, but not enough to be alarming. The uterus was not firmly contracted, but the patient felt strong. Her diet was increased. On May 15, or the fifth day, she had a severe hemorrhage. The uterus was relaxed. Vaginal examination showed some cervical laceration with ragged edges and an open os, large enough to admit the index finger. She was given a hot saline douche and 25 drops of aromatic sulfuric acid in a tumbler of water. The vagina was packed with gauze and sterilized napkins completed the toilet. I left her feeling comfortable, with the uterus contracted, but not firmly. On May 16 I removed the gauze and dressed with only sterilized napkins. In the afternoon she had a severe hemorrhage. Thinking that there might be a blood-clot or a part of a retained placenta in the uterus, I douched the uterine cavity with a hot saline solution through a spoon-curet, bringing nothing forth, not even clotted blood. I packed the uterus lightly with gauze to

cause, if possible, forcible contractions. During the evening the gauze was removed because it produced intense pain. I examined the uterus and found the cervix closed. On May 17, at 2 a.m. she had a hemorrhage that nearly exsanguinated her. When seen she was in a state of collapse, respiration and pulse rapid, and cold sweat standing out over her body. The foot of the bed was raised quickly, three feet from the floor. Placing my hand over the abdomen I grasped the uterus contracting it down. I administered aromatic sulfuric acid, 25 drops in a tumbler of water, and ordered tumbler draughts of normal saline solution to be given every half-hour. In two hours she had recovered somewhat from the shock and felt better. Her uterus had contracted, but not strongly. She was given a saline douche and dressed with napkins. I was called at 6 p.m. and found my patient pulseless, gasping, and blood everywhere—mattress soaked, quilts soaked, and a pool of blood on the floor. The foot of the bed had not been lowered. Again I placed my hand on the belly to grasp the uterus but it was gone. Quickly administering brandy and aromatic sulfuric acid in water, she was ordered strong coffee and was given large draughts. Somewhat recovered, her husband was told to give aromatic spirits of ammonia by the teaspoonful every few minutes. I then examined the genitals and in trying to enter the vagina I found it blocked with something hanging between the thighs. Running two fingers in between the mass and the walls of the vagina, about two inches downward and backward, I could map out a ring to whose edges was attached something. Requesting a neighbor to hold a lamp, I found a pear-shaped spongy organ, whose outer coat was gangrenous. It was movable, pendulous, spongy, and large. It flashed through my mind that I had an inverted uterus, and so it was. The mucous surface bled easily even on the merest touch. With the head lower than the heels, the foot of the bed being raised, I grasped the inverted uterus and pushed it downward and backward, but a gush of blood bathed my arm and hand. Loosing my grasp, I wrapped gauze and cotton around the uterus and tried to replace it, but it would not replace. My patient was gasping, and suffering terrible shock. Believing discretion the better part of valor, I applied more gauze and cotton, and covered with a sterilized napkin, and began to apply restoratives. In two hours she was considerably relieved. Again I tried to replace the uterus, but the large boggy mass would do nothing but bleed. Knowing that if I could reduce the size of the uterus, it would probably go back, I showered it with four gallons of hot saline solution. I then made a sling of three layers of iodoform gauze, tucked one end into the space between the posterior wall of the vagina and uterus, bringing it under the uterus and over its fundus along the upper surface of the uterus, and tucked the end into the space between the uterus and anterior surface of the vagina. The uterus was now covered with gauze. Rolling absorbent cotton into two rolls, I applied one under the uterus into the vagina and crowded it down against the tucked end of the gauze as hard as I could. The other end I applied on top of the uterus into the vagina against the other end of the tucked gauze, and pressed it downward as hard as I could, placing a tension against the inverted fundus and uterus; also compressing the superficial bloodvessels. I finished the toilet with sterilized napkins. Large draughts of normal saline solution were given every half hour. I left her at 9 a.m., feeling better, with a temperature of 99°+, pulse 105, and respiration 26. I saw her again at 3 p.m. She was stronger, no hemorrhage had taken place, and the temperature was 101°+, pulse 85, and respiration 20. She had had no chill. The inverted uterus was showered with four gallons of hot saline solution. Gauze was again applied as above described, and rolls of cotton and wool tucked into the vagina as before. I continued the saline draughts, and at 9 p.m. she was treated again in the same way, and left in the hands of her husband and a neighbor, with orders to give saline-solution until 3 a.m., and then let her sleep until 6 a.m., when they should again give the solution.

On May 18, at 6 a.m., her temperature was 100°, pulse 80, and respiration 18. She had rested well during the night. There was no hemorrhage, but a bloody watery discharge from the lining of mucous membrane, that smelled badly. She had passed a quiet night, and was without pain. Inspection showed gangrene of the membrane covering the mucous membrane of the uterus. I showered the uterus with

a hot mercuric chlorid solution, 1 to 2000, four gallons of solution being used. The sling of gauze was applied and its ends tucked into the vaginal space with rolls of cotton and wool, until tension was placed on the fundus, crowding it downward and backward. Sterilized napkins completed the toilet. Saline draughts discontinued, and she was placed on hot milk, a tumblerful every three hours. The bowels had moved, and urine had been passed in large quantities. At 6 P.M. the temperature was 99°, pulse 80, respiration 18, and the patient felt stronger. The discharge from the uterus was offensive. There has been no hemorrhage and no pain. The uterus was showered again with four gallons of hot mercuric chlorid solution, 1 to 2000, and dressed as above. At midnight her temperature was 99°, pulse 90, respiration 18. She had slept a little. There was an offensive odor from the uterus. It was again showered with four gallons of the hot mercuric solution and dressed. The uterus was less spongy.

On May 19, at 8 A.M., her temperature was 100°+, pulse 90, respiration 20. The watery discharge from the uterus was offensive in odor. The inverted womb was showered with four gallons of hot mercuric solution, 1 to 2000, and dressed. She complained of some pain across the belly. Diet: Gruel, broths, and milk. Before placing the sling of gauze over the uterus, the womb was dusted with iodoform 1 part, and boracic acid 3 parts. At 5 P.M. the womb was showered with the hot solution; the watery discharge was lessened, the membrane detached in spots, and the odor gone; the temperature was 101°+, pulse 30, respiration 18. She felt strong, but had some abdominal pain. Her bowels had moved and she had passed urine freely. The uterus was smaller and less spongy, and there was no hemorrhage. The vaginal space was greater, large rolls of cotton and wool were used, and more tension placed on the gauze sling. She was left for the night.

On May 20 the temperature was 100°+, pulse 87, respiration 18. She had rested well during the night. There was no hemorrhage, no odor, and the uterus was firmer. Some parts of the membrane were detached from the uterine mucous membrane, but some three spots of the membrane were yet gangrenous. I showered the uterus with four gallons of hot saline solution and dressed as before.

At 6 P.M. her temperature was 99°, pulse 86, respiration 18. She felt comfortable, had taken considerable nourishment during the day. The same treatment was carried out.

May 21 the temperature was 98.5°, pulse 78, respiration 18. There was no odor, but some watery discharge from the uterus. I detached more exfoliated membrane, but there was no hemorrhage. She slept well during the night. The uterus was treated as before. It was smaller and firmer, and the vaginal capacity was increased by the uterus receding in the afternoon. I gave the uterus another douching. The temperature was 100°, pulse 85, respiration 18. She had no pain, had passed a good day, and had taken considerable nourishment. I gave her $\frac{1}{2}$ grain of strychnia.

May 22. She had passed a good night, and the uterus looked clean, shrunken and wrinkled, receding into the abdomen. It was dressed as usual. I tried to replace the uterus, but failed because of much pain in manipulating it.

On May 23 the morning temperature was 99°, pulse 85, respiration 18. She had passed a good night, but had some abdominal pain. The bowels had not moved for 30 hours. The uterus was douched and an enema of soap and water was given and the bowels moved. Urine was freely passed. I gave her another dose of strychnia. In the afternoon the temperature was 100°, the pulse 90, respiration 18. She felt well, had no pain, and the bowels had moved freely. The uterus was dressed as usual. It had shrunk to half its former size, and was receding, the vaginal capacity being increased. Larger rolls of cotton and wool were packed into the vagina, producing tension on the womb.

Improvement was progressive until May 27 when the length of the vagina was $\frac{3}{4}$ inches anteriorly and 4 inches posteriorly; the uterine toilet was continued.

On May 28 the uterus was nearly normal in size. I placed the patient in a Trendelenburg position, and pushing the uterus downward and backward, it went into the abdomen with a rush and a snap. I tamponed the vagina lightly, and made her diet liberal. The next day she sat up for a while. I visited her May 30 and 31, June 1, 3 and 5, when she was discharged. I examined the uterus that day. It was mobile, and free from pain or displacements.

I had the patient under observation after her recovery for over a year. She was in good health, but during the year she did not become pregnant.

It may be interesting to observe the pathology of this case. I believe that hemorrhage weakened the muscular fibers of the uterus and the muscles of the pelvis. The uterus, weakened in its natural support, became inverted because of its weight.

In complete inversion, where are the ovaries and appendages? They must lie by the side of the sacro-uterine ligaments and between the muscular walls of the uterus. One could expect that the ovaries would be displaced. But in this case the ovaries were in their normal relation to the uterus after it was completely reduced.

In some cases of inversion, amputation of the uterus has been resorted to. I wish to introduce a new instrument for reducing inversion when all else has failed, to take the place of amputation. It is a pair of long, slightly curved forceps, barbed on the end like a fish-hook. An abdominal incision exposes the cavity of the inverted uterus whose walls are the uterine muscles. Introduce the forceps, passing them to the fundus, spread them apart, catching the barbs into the muscles of the uterus and producing traction, draw the uterus back into the abdominal cavity, at the same time putting tension on the fundus. I believe this operation safe and feasible, preferable to amputation. If by mishap, the uterine wall is torn, it is an easy matter to stitch it. I can conceive of no case of inversion, seen at the time of the accident, requiring amputation, except when the uterus is the seat of large fibroids or malignant growths.

Partial uterine inertia is frequently met. Complete inertia is rare. We frequently meet cases in which labor is prolonged because of lack of forcible labor action.

During the month of July, 1896, I was called to confine Mrs. G., aged 22. She had been in good health all her life. She had been married nearly a year, this being the first pregnancy. She was well developed. Labor-pains had begun upon my arrival.

It was twin pregnancy. After many hours of short nagging pains her first child was born. It lived but a few hours. Labor-pains stopped. I tried many ways during the preceding hours to induce labor, but failed. I once heard an old lecturer say that "God never forgot the pregnant woman, and sooner or later labor-pains would come." I spent 8 hours with her, waiting for labor-pains. At the end of the time, I tamponed the vagina and placed her on oxytocics, to be given every hour. I retired for the night. They were to call me when labor recommenced. The next morning brought no labor-pains, nor any during the day or night. There had been no hemorrhage and the patient rested quietly, feeling well. Upon the third day, in consultation with Dr. Cassidy, anesthetics were administered, and carrying my hand into the uterus to its fundus, I ruptured a sac and delivered a dead fetus and an adherent placenta. The mother made a good recovery without untoward symptoms. She has never been pregnant since, but is in excellent health. I have never been able to explain the cause of the inertia.

In the fall of 1898, I confined a woman of a healthy boy, whose umbilical cord was only 9 inches long. Under forcible pains the head advanced slowly and upon the birth of the head, the face was very cyanotic, a condition which frequently means cord compression. Upon examining the child as quickly as possible, I discovered an unnatural bulging at the umbilicus, the placenta lying upon the abdomen. Not knowing exactly the condition I had, I ruptured the cord, and quickly delivered. I caught the torn cord with an arterial forceps in mass and ligated. The placenta was expelled and upon measuring the cord it was found to be only 9 inches in length from the umbilicus to the placenta. Artificial respiration resuscitated the child. The mother and child are both living and in good health.

A FEW CASES OF DIPHTHERIA AND WHAT THEY
TAUGHT ME.¹

By JOHN LEVERETT, A.B., M.D.,

of Binghamton, N. Y.

STATISTICS in regard to diphtheria and antitoxin have already been furnished by the larger hospitals, and to such statistics these few cases will be but a drop in the bucket. But I find that many general practitioners are still somewhat sceptical about its value and timid about using it. For them I hope the experience of a general practitioner, situated very much like themselves in an inland city, may prove of service. The bacteriologic examinations mentioned below were made by the regular bacteriologist employed for such purpose by the Board of Health of the city.

CASE 1.—April 13, 1899, I was called to see a young man about 21 years old, who was suffering from a sore throat, both tonsils being covered with an exudate having every appearance of diphtheria. A culture showed plenty of the Klebs-Löffler bacilli, and on the receipt of the report 1000 units antitoxin was injected. Much to my surprise the membrane disappeared as if by magic, rolling up from the edges, and in 48 hours the throat was clear. Well pleased with the result, I had a culture examined on the fourth day in order that he might be relieved from quarantine, and again to my surprise found that the bacilli were still present. By this time the young man felt and appeared perfectly well, but not until the thirteenth day had the germs disappeared.

CASE 2.—February 1, 1900, I was called to see a young married woman about 19 years old, who was complaining of pain in her head and back and whose temperature was between 104° and 105°. On my second visit she remarked that her throat felt queer. I found it covered with exudate, and a culture showed it to be diphtheric. On receiving the report (which means about 12 hours after the culture is obtained), she was given 1000 units of antitoxin with the result of causing the membrane to disappear in about 36 hours. But in her case the temperature still persisted for several days, coming down by lysis. Not until the thirteenth day did a culture show the absence of the germs.

In both of these cases the attendants received an immunizing dose—500 units—of antitoxin, and no other cases developed. Of course, after these two cases I felt very much pleased with the treatment and much confidence in its efficacy. But in neither of these did I know, nor could anyone tell, that they might not have run a more or less benign course without treatment. But in the group of cases that follow I think that I am justified in saying that the infection was of the most virulent form.

CASE 3.—February 15, 1900, I was called to see a little German girl, Rosie K—. She was in bed with her sister Katie, in fact I had been called to see both of them, but Katie seemed to have only a cold and I could see nothing suspicious in her throat. Rosie, on the other hand, was decidedly croupy and showed a suspicious throat. A culture was taken and diphtheria was the verdict. Meanwhile I had been giving what remedies I could to relieve the croupy condition but without avail, so, on the second day, being sure that I had a case of laryngeal diphtheria, she was given 1000 units antitoxin. But no marked improvement took place, and the next afternoon, the breathing getting worse instead of better, she received 2000 units more. That night she died. She did not strangle to death as I expected she would, but the attendants said that she breathed easier for a short time before death. Still I lost my patient in spite of the antitoxin.

CASE 4.—The other child, Katie, who had occupied the bed with Rosie on my first visit, had been removed to a room in another part of the house, and on my second visit I was informed that I need not see her as she was better, so

she was out of my mind. The day after Rosie died I was called to see Katie. Her throat was covered with a mass of blood-stained membrane. But I was a little discouraged in the use of antitoxin, and it seemed to me from appearances that the disease was then at its height and already self-limited, and she was treated without it. As I look back upon it now I don't believe that, given at that stage of the disease, it would have altered the result. She was treated with good-sized doses of tincture of chlorid of iron, heart tonics, stimulants, nourishment, and antiseptic throat irrigations. The membrane peeled off and was coughed up in due time, and I hoped she would get well and so told the parents and, in fact, diminished my visits from two to one a day. Two days after the membrane had disappeared the heart's action became bad and on the 26th she asked her father to hold her in his arms for a few minutes, and while in his arms, without any warning her head fell back and she was dead. No bacteriologic examination was made in this case; none was necessary.

CASE 5.—While this last patient was sick, about six days before her death, they asked me to look in the throat of her little brother Johnny, aged 4 years. I found both tonsils covered with a characteristic membrane. Without waiting longer than to send to the drug store for it, I gave him 1000 units antitoxin, and the next day he was feeling well and part of the membrane had come off. The day after the throat was clear. The culture taken the first day showed plenty of the Klebs-Löffler bacilli and they still persisted, for it was not until the sixteenth day that the throat was free from them. During none of this time was this child sick enough to be confined to the bed.

CASE 6.—March 3, five days after Katie's death, I was called to see the oldest daughter, Sophie, aged 18 years, and found her tonsils covered with a membrane which was afterwards proved to be diphtheric; 1000 units of antitoxin were immediately administered and she went to bed. The next day the throat began to clear up, and on the day following was entirely clear. The bacteria in her throat persisted for about 16 days.

When she was taken sick the other members of the family, father, mother, and big brother, received each 500 units for immunization, with the exception of the baby, then a year old. None of those so immunized contracted the disease.

CASE 7.—About the same time that Sophie, the older girl, was taken sick, my attention was called to the baby's eye, which was badly swollen and discharging profusely. I advised them to see an oculist, and Dr. McFarland was called, who pronounced it a diphtheric conjunctivitis and took charge of the case. On March 5, having discontinued my visits, Sophie being convalescent, I received word that the oculist said I should see the baby. I called on the doctor immediately and he said that the throat was then full of membrane, although the conjunctivitis was improving, and that in his opinion it would go hard with the baby that night. I went down and found it as he had said, a culture taken at the time showing the characteristic germs. I immediately gave the child, aged 1 year, 800 units of antitoxin with the happiest results. He had a comfortable night, the membrane had begun to come off in the morning, the day following there was no membrane left and in 14 days the throat was clear of germs. This was the last case in that family. My remarks on these cases I will reserve for the end of the paper.

CASE 8.—March 12, 1900, I was called to see a girl, 12 years old, in another part of the city. Both tonsils and the uvula were covered with what, to me, seemed an undoubted diphtheric membrane, but her aunt, with whom she was living, and who seemed to be very intelligent, said that she was accustomed to have that kind of sore throat several times every winter, in fact had suffered from it but a month or so before, when the membrane looked the same and was, in fact, more extensive. She had then been sick for two or three days, and although her throat felt bad she was very averse to staying in bed. I prescribed iron, using in this case the pyrophosphate, and the throat was also frequently swabbed with an antiseptic. A culture taken on my second visit showed Klebs-Löffler bacilli. No antitoxin was used in this case for the following reasons: The case was so ad-

¹ Read before the Broome County (N. Y.) Medical Society, April 3, 1900.

vanced when a positive diagnosis was made that there would have been little chance of its favorable action, and, since the family were still fully convinced in their own minds that she had nothing more than she had had many times before, if, in these circumstances she had been given antitoxin and died in spite of it, they would have felt sure that she died because of it. But the membrane cleared off leaving a gray scar behind. Then vomiting commenced and her pulse became weak in spite of stimulants which she was taking. I quieted the vomiting somewhat and stimulants improved her pulse, when, contrary to my orders they gave her a large drink of water, she immediately vomited it up, fell back, and died.

CASE 9.—March 27, 1900, I was called to see a baby, aged 3 years. Both tonsils were covered with a thick exudate and a culture showed Klebs Löffler bacilli. The next day, when I received the report, I injected 1000 units antitoxin. The day following there was not much change in the appearance of the throat, but the day after that there were only a few tags of membrane left and his mother said that he had been playing horse with two chairs most of the morning. The further convalescence was uneventful.

Other cases I might quote in which antitoxin in my hands has been uniformly successful, but these have been selected because they have been very instructive to me and I hope will be to others. From the reports which I had read in regard to antitoxin I was in more or less doubt as to its value. Until I have a further and a different experience I shall now try to use it in every case which comes into my hands early, and I shall feel much more confidence in the ultimate results.

The first case in the German family was fatal although antitoxin was used, but it was a laryngeal case, and a laryngeal case is so far advanced when it is diagnosed diphtheric that antitoxin is apt to be useless. In the 3 cases which recovered in this family, and that almost without symptoms excepting the membrane, no one, in view of the 2 who died, can say that it was a mistaken diagnosis or a light form of infection. Besides, there were several other deaths in the neighborhood in the same epidemic.

A physician recently said to me that if he had a case of diphtheria which he was afraid was going to die, he would use antitoxin as a last resort. I told him, as I say here, that he would generally have his trouble for his pains, for, if antitoxin is to be of any service, it should be used in the first few days of the disease, before the poison has been thoroughly absorbed into the system. Then the membrane may be expected to clear off inside of 48 or 60 hours and all the symptoms to subside. The patient is not and has not been poisoned, and you know, if you have ever had much real diphtheria, what I mean by that. In this connection I would call attention to the fact that the 2 cases that did not receive antitoxin died from systemic poisoning after the membrane had entirely disappeared.

These cases have also brought forcibly to my attention a fact which has not been sufficiently emphasized in view of its importance as regards the spread of the disease, namely, that the bacilli persist after the patient is clinically well if the case has been treated with antitoxin. I took a culture which still contained the bacilli from the throat of the older German girl, (Case 6), when not only had her throat been clear for several days, but she was downstairs attending to the housework. It is easy to see how such cases might be an unsuspected source of infection. It seemed to make very little difference what local applications were used, although, of course, no culture was taken immediately after an antiseptic application. Case 8 shows well the

value of a bacteriologic examination for diagnosis, especially in those patients who are subject to sore throat, and who are liable to let a case of diphtheria run because they think it is the same thing that they have had so many times before. It, and certain negative cases not here reported, taught me that when I find a suspicious-looking sore throat, I should have a culture examined immediately, no matter what the previous history, and should then be guided in my treatment by the finding of the bacteriologist.

In 2 of the cases I was able to trace the probable source of infection in a very interesting manner. In Case 1, the young man probably took it from his mate in the factory, who had stayed from work a couple of days with a sore throat but had had no physician. He said that they were accustomed to chew from the same quid of tobacco. In Case 9, the history on that point is interesting. This baby was visiting some friends in another street and while there was taken sick. They called their own doctor and, so they say, he pronounced it worms. I saw the other doctor the day after the diagnosis of diphtheria was confirmed and told him about it. To my surprise he laughed and said that he had expected it, as they were just recovering from an attack of diphtheria in the family when this child came there to visit. He had not reported his case as it was light and the child recovered. He seemed to think that it was a pretty good joke.

There are some members of the profession who have never used antitoxin, and for their benefit I will answer one or two questions which were asked me by a brother physician. Write a prescription for it and let the patient buy it at the drug store unless his credit with you is gilt-edged, when you can save a little time by buying it yourself and charging it up to him. It is not expensive. To a man who intends to pay his doctor's bill, \$1.50 for medicine which will save him a long and dangerous sickness and perhaps \$10 extra doctor's fees, it is an economy. To inject it an ordinary hypodermic syringe may be used, and it is best injected under the skin of the abdomen or loins. With a 30-minim syringe the needle will have to be inserted four times to inject 1000 units standard. Inject slowly and less pain will be caused as I know from personal experience. The quantity for a suspected case should be at least 1000 units. The syringe may afterwards be cleansed with warm water and sterilized by drawing it full of pure carbolic acid.

POSTDIPHTHERIC PARALYSIS OF BOTH EXTERNAL RECTI MUSCLES.—REPORT OF A CASE.

By HARRY FRIEDENWALD, M.D.,
of Baltimore, Md.

MYRTLE S., aged 6 years, was very ill with faucial diphtheria on January 19, 1900, when her physician, Dr. H. Lee Franks, was first called in to see her. On that day he injected 2,000 units of xx antitoxin and did the same on January 21, making 4,000 units concentrated. He discharged her as cured January 30.

On March 7 he sent the child to me for examination, because convergent strabismus had developed. I found almost complete paralysis of both external recti muscles, and also of the palatal muscles, which had developed in the last few days. The head drooped upon the chest from paresis of the cervical muscles. There was no paralysis of accommodation. Syrup of iodid of iron was ordered. I saw her again on March 15, when the condition was unchanged. On March

22, I found well-marked paresis of both upper and lower limbs. I did not see the child again until April 14, at which time I found that the child had recovered completely from all the paralyses, and I was informed that the eyes had become straight a few days after I had last seen the patient. The paralysis of the external recti muscles had therefore lasted a little more than two weeks.

Remarks: This case presented a number of interesting features. First of all I should like to call attention to the extent of the paralysis, involving the palatal, both external recti muscles, the muscles of the neck, of the upper, and of the lower limbs. The first signs of paralysis made their appearance about 5 weeks after the local inflammation had entirely disappeared. The paralyses did not set in at the same time, the palatal paralysis and that of the external recti muscles having been the first to appear, and they passed off in the same order in which they had come on, each lasting between 2 and 3 weeks.

Postdiphtheric paralysis of the external recti was formerly believed to be of very rare occurrence. That this is not the case appears from the statistics in Hirschberg's clinic. Moll¹ in 1896 collected 150 cases of postdiphtheric paralysis affecting the eye, that had appeared at the clinic during the previous 10 years. Of these 150 cases showed a paresis of both external recti, and there were 3 cases of paralysis of a single external rectus. The frequency of paralysis of the external ocular muscles is still better shown in the report of Goodall based upon 1,071 cases of primary diphtheria under treatment at the Eastern Hospital, Homerton, during 1892 and 1893.² Of these 362 cases proved fatal from the primary disease; of the 709 surviving patients 125 developed paralysis. "In 102 cases the palate was paralyzed; in 56 the ciliary muscles; in 52 the lower extremities; and in at least 11 the muscles of the larynx." "Of the 26 cases in which the external ocular muscles were affected, in 14 the notes only state the presence of squint, without specifying the exact muscle or muscles paralyzed. In 7 of the remaining 12 cases, one external rectus (usually the left) was paralyzed; in 3, both external recti; and in 2, most of the muscles of the eyeballs. In none of the cases were the internal recti affected apart from the external. In one case there was ptosis."

It is a matter of much interest to know what effect the serumtherapy has had upon the development of postdiphtheric paralysis. Soerensen³ has investigated this subject and found that "in 34 cases of diphtheria treated with serum, 20 cases were affected with paresis, while in 31 cases treated without serum he observed paresis only in 16, and the former were even more complicated than the latter."

Escherich⁴ and later Gutmann⁵ also concluded that the serumtherapy is more frequently followed by paresis, and that this is more apt to be severe in the serum cases.

Greef,⁶ whose views are in accord with the above, explains the relative increase and severity of the paralysis as the result of the much greater ratio of recovery in severe cases because of the serum-treatment. Many cases now survive and develop paralysis which formerly would have died. The case related perhaps belongs to this number.

In conclusion, it is interesting to note that serumtherapy has been applied for the postdiphtheric paralysis in a relatively small number of cases, but the results are very indefinite and scarcely encourage further experiments in this line.

Rupture of the Popliteal Artery.—Bloodgood (*Maryland Medical Journal*, September, 1900) reports the case of a youth of 19 who suffered a posterior dislocation of the right knee-joint, with subcutaneous complete transverse rupture of the popliteal at its bifurcation. There was plugging of the artery by a thrombus, and no hematoma formed in the popliteal space. There was thrombosis of the popliteal vein, and gangrene of the leg set in soon after the injury. There was no great loss of blood, but shock was extreme 3 hours after the injury, when the patient was admitted to the hospital. The patient was kept under observation for three days; the temperature rose to 104°, and leukocytosis to 8000, due probably to fibrin in the blood, as the gangrenous tissues were sterile. Amputation through the condyles of the femur was performed on the third day. The patient made a good recovery. [A B C.]

Methods of Resuscitation in the Newborn.—Ayers (*Obstetrics*, August, 1900) remarks that proper application of means of resuscitation requires much judgment. Some children which suggest the need of resuscitation should be wrapped up warmly and left absolutely quiet. Such are generally those yet under the influence of drugs given the mother—ether, chloroform, morphin, etc. Regarding the many methods advocated for restoring circulation and inducing respiration in the newborn, the following is urged as altogether superior in all respects. It may be termed the "subaqueous method." When the child is born, and while the cord is yet intact, bring a large bowl or a bath-tub filled 6 inches deep with hand-enduring hot water, close to the mother and immerse the child in the water, holding the babe with its head, neck, and shoulders resting in the palm of one hand, and its knees in the palm of the other hand. Keep the face out of the water. Keep the cord free from interference with its circulation. Do not handle it. To expand the chest bend the entire body backwards, and to compress the chest reverse this motion. To stimulate voluntary respiration and crying, lift the child out of the hot water and dip it into a second bowl of cold water, and then immediately return it to its hot-water bath, and repeat the chest expansion and compression. Repeat the cold-water dip after several seconds. Remove the mucus from the mouth and throat with a piece of gauze on the end of the finger. An assistant can better do this. In some cases, having inhaled mucus, it may be well to lift the child by the feet for a few seconds to let the fluid run into the mouth. Spanking is of occasional value, and, rarely, the introduction of a catheter into the bronchial tube. When cold-water dipping fails to secure voluntary respiration, place a piece of gauze over the child's nose and mouth and expand the lungs by placing the mouth over the child's mouth. Regulate the force of this mouth-to-mouth lung inflation, aiming to do it quickly, but not to rupture the child's air vesicles. By Schultze's method the child's cord is cut promptly, the physician grasps the shoulders, holding the body forward, and swings it forward and upward until the limbs and pelvis fall by gravity upon the chest and compress it. Swinging the body back again the chest is expanded. While this method is undoubtedly effective in expanding the chest and in stimulating the respiratory center by exposure of the skin to the air, it is so unnecessarily severe and sacrifices so many important features the writer thinks it should be abandoned. Animal heat in the newborn will be lost very rapidly in one that is asphyxiated. The subaqueous method preserves animal heat so long as needed. This method secures as good chest expansion and compression as does Schultze's. It does not require severance of the cord and gets the benefit of continued placental circulation. The cold-water dip gives full skin stimulation without causing the loss of animal heat. The hot-water bath is especially useful in the semi-narcotized and in the pallid classes. When the child is first immersed in the hot-water bath its skin will turn blue, due to dilation and temporary blood stasis in the capillaries. It is of no importance. Traction of the tongue will stimulate respirations, also slapping of buttocks. The pallid child may need a drop or two of whisky or brandy. [W. K.]

A Grateful Constituency.—If the newspapers are to be credited, one of the Congressional districts in Maine has just been the scene of an election for Congress that is probably without precedent in this country. The chosen candidate is an invalid in a hospital for the insane, where he has been detained now for nine months. He is well known in public life as a faithful and able legislator, for he has already served for some years in Congress, and the feeling of regard and sympathy for him in his home-district is reported to be so great that even his political opponent did not attempt to make much of a canvass, for fear of the prejudice and criticism with which he would meet. From the medical standpoint the situation is abnormal and not to be highly commended, since it is against medical instinct to impose public trusts and obligations upon a man who is unfortunately deprived of the full use of his mental faculties; but the motive which has inspired this nomination, while it may be sentimental, is certainly a worthy one, and goes to prove that republics are not always ungrateful. What medicolegal relations the case may have we do not yet quite see; but if the congressman-elect should attempt to take his seat before he had made a complete recovery, there might, we should think, be some interesting questions raised. The friends and supporters of this unfortunate statesman are possibly assuming some large responsibilities for him and for themselves.

The Medical Martyrs.—Medicine has her martyrs, and they are no less worthy of commemoration than those of religion. There is, unfortunately, little reason longer to doubt that young Dr. Courtland Van Rensselaer Hodge, and possibly Dr. Yardley Taylor, have met with a martyr's fate in the insurrection in China. Intelligence is meager, but the American minister has cabled a few words which are all too fateful to the ears of waiting and mourning friends. For the immolation of these young physicians, and of the fair wife of one of them, there will be an universal feeling of mingled execration and sorrow. It is no place here to estimate the advantage gained, and to compare it with the price paid, in the missionary enterprises in China; but surely no one can read or think of this frightful sacrifice, made by a little group of Americans, who represented some of the best blood and culture of the land, without a sense

of its unutterable pathos; and no member of the medical profession but must feel that in this martyrdom he has himself a privilege and a share. For these young men and this young woman at least went out with none but the motives of a pure altruism, and sought to scatter in a land that sorely needs them the seeds, not of a militant and narrow theology, but of a broad and universal science. Their mission was a propaganda of benevolence; their death is a tragedy that disgraces one race, while at the same time it ennobles humanity. If it be indeed true that hope is ended, and that the final word has come that notes their cruel destiny, their memories are entitled to the homage of a profound reverence, and their friends to a sympathy that can only inadequately be expressed in words.

The Galveston Disaster.—When the first reports of the destruction to life and property by the fearful hurricane which struck Galveston on September 8 were sent out, it was confidently hoped that they were greatly exaggerated. Each day, however, brings additional confirmation that the original statements were in no wise overestimated, but rather the reverse. Never before in the history of our country has such a disaster happened to any community. The loss of property will reach far into the millions, but the loss of life is now known to be appalling, and even yet it is feared the whole truth is not known. As hundreds of bodies were washed out to sea, never to be recovered, the number that perished can never be more than approximated. It is now variously estimated at from 5,000 to 10,000.

At this date the recovery and disposition of the dead bodies goes on rapidly. This work is rendered especially difficult by the fact that over considerable areas most of the buildings were completely wrecked, burying the unfortunate occupants beneath them. It is now proposed by the authorities to burn certain districts of the city, and thus dispose of the decaying bodies and the wrecked buildings. The unsanitary conditions brought about by these circumstances and by a partial cutting off of the water-supply can hardly be overestimated, and the fear of a general pestilence has been great. The chairman of the Texas State Board of Health and the members of the City Board of Health of Galveston have given assurances, however, that they regard no such danger as imminent.

The generous manner in which the whole country has responded to the needs of the stricken sufferers is deserving of applause. The larger cities have vied with each other in answering the call for aid. From every quarter trainloads of supplies, medicines, and disinfectants have been rushing on to Galveston. Physicians and trained nurses by hundreds have volunteered their services, and many have been sent to care for the suffering.

All indications point to the rebuilding of Galveston. Its commercial importance is great, and it appears that the people have no idea of abandoning the city's site. Doubtless, a fairer, better, healthier, and more stable city will be erected on the ruins.

Sir William Turner.—It is a subject for congratulation that the British Association for the Advancement of Science has had for its president this year a distinguished member of the medical profession. This Association stands in the foremost rank of learned societies and represents practically all departments of science. It is, therefore, not specially representative of medical research, and in its wide inclusiveness of all branches of science, it might be feared that the medical sciences, although among the most important of the physical sciences, would stand some risk of occupying with it at least a not conspicuous position. This has not been the case, however, with the British Association, for its meetings have frequently been the occasions for important contributions to medical learning. In other words, medical science, in its wider sense, has held its own in generous rivalry, as it were, with the other sciences, some of which are but remotely, if at all, related with it. This fact is due to the eminence of the members of the British medical profession, who are affiliated in this Association with scientists of wide note in other fields. There are certainly many advantages to be gained by such affiliation, and the conspicuous rank accorded to medical investigation in the British Association for the Advancement of Science must be a source of satisfaction to all members of the profession. None more worthy than Sir William Turner could have been selected to preside over this distinguished assembly. He has held the position of president for the current year, and an abstract of this very able presidential address has just been published in the *British Medical Journal* (September 8, 1900, p. 690).

Sir William Turner's work as an anatomist has placed him in the very first rank in this field. He succeeded Professor Goodsir, in 1867, in the chair of anatomy in the University of Edinburgh, and his contributions to science and his accumulated honors are too many to be enumerated here. We merely wish to congratulate him as well as the medical profession on the honor which has been done both to him and to it—an honor which he has most capably upheld. It is to be noted that he succeeded in the presidential chair another

eminent medical scientist, Sir Michael Foster, the physiologist.

Surgical Opening of a New Side Track for the Blood of the Portal Vein.—In those cases of cirrhosis of the liver which cause obstruction of the portal circulation clinicians have occasionally observed cures resulting from the natural establishment of collateral circulation. Nature usually makes an effort at relief of the condition, giving rise to the caput medusæ, which is a commonly recognized symptom of this affection. Within the past four or five years various surgeons have tried to bring about this result artificially. Drummond and Morison (*British Medical Journal*, September 19, 1896) were probably the first to report an attempt of this kind, and of two patients who were operated upon one recovered. Morison has recently reported a second successful case (*Lancet*, May 27, 1899). Recently a number of other surgeons have performed similar operations, many of them without knowledge of the work of others. In the *Berliner klinische Wochenschrift* for July 30, 1900, Talma, of Utrecht, reports two cases in which such an attempt was made, and about a year previously he reported a similar successful case. A man, 59 years old, was taken with symptoms of cirrhosis of the liver following chronic diarrhea, the cirrhosis having resulted from infection from the intestine. The abdomen was repeatedly tapped and large quantities of ascitic fluid were withdrawn; the liver could be felt enlarged, hard and nodular, with an irregular edge; the patient became delirious from cholemia. Having observed a favorable result following operation in a similar case, operation was advised and was performed by Nareth. On opening the abdomen the parietal peritoneum was found to contain many enlarged veins, and numerous, tortuous, enlarged veins were seen in the omentum. The liver was very hard and nodular, with a blunt edge and thickened serosa. The serous surfaces were gently sponged and a number of sutures were taken uniting the omentum to the peritoneum of the abdominal wall. The patient continued in a delirious condition for some time, but the ascites did not recur and gradually complete recovery followed. At present the man is comparatively well and able to work at his usual occupation. In a second case of chylous ascites with cirrhosis of rapid development, operation was performed under local anesthesia with Schleich's solution. The ascites recurred, however, and death followed soon after the operation. At the necropsy numerous enlarged veins were found at the place where the omentum had been stitched to the parietal peritoneum.

In all, seven or eight cases have been recently reported in which operation has been performed for cirrhosis of the liver causing obstruction to the portal circulation. About 50% of the patients have died, but several very satisfactory recoveries have resulted, some

of them as striking as in the case just reported. While the results cannot be considered very encouraging considering the very slight chance of the establishment of collateral circulation by natural means and the almost certainly unfavorable termination of the disease without such collateral circulation is established, so simple a procedure can scarcely be considered unjustifiable.

Smallpox in the United States.—The fact has not infrequently been noted that smallpox has been prevailing for some time past in the United States in an unusually mild form. In fact, there have been reasons to suspect that in some quarters the genuine disease has presented itself in such a mild type that it has either not been recognized or else passed off as a less serious disorder. The official statistics of smallpox in this country for the past few months, as published in the United States Marine-Hospital Service, exhibit this subject in such a panoramic way that we present a brief synopsis of them for the benefit of general readers, and also possibly for the enlightenment of the few unfortunates who continue to oppose vaccination. In Alaska there was a small epidemic this summer, chiefly at Cape Nome, of 28 cases, without a death. In Colorado there has been an epidemic thinly spread over 15 counties, with 109 cases and no deaths. In Indiana also there has been a widespread prevalence of the disease with only 130 cases and 5 deaths during the months of June and July. In Louisiana a more severe type of smallpox has prevailed, for in June, July, and August, 148 cases with 40 deaths were reported. In Minnesota there was still more of the disease, but the mortality was astonishingly low—283 cases with only 3 deaths. North Carolina had 440 cases spread widely over the State, with not all cases reported, and yet the death-rate was very small. Ohio has had plenty of smallpox since the beginning of the year—1,376 cases—and yet has lost but 17 persons from the disease. Texas, with 556 cases since February, has lost only 4 patients. It will be seen from these statements that the disease has been quite widely spread over the United States, but has prevailed more in some localities than in others. Few States have been exempt from it, but in all of them, with the exception of Louisiana, the death-rate has been (if the term is allowable) abnormally low. In the Middle States—Pennsylvania, New York, and New Jersey—there has been but little smallpox in proportion to the large population, and only *two deaths* in these three States all summer. The grand total of cases for the United States for the period covered (which is mainly the summer months) is 3,818, with only 114 deaths. This seems almost incredible.

In view of these figures, and with our attention so much occupied with plague, yellow fever, and cholera, we are likely to lose sight of the fact that smallpox was formerly one of the great scourges of the human race.

Surely it is not too much to claim that most of the credit for this change is to be found in vaccination, by which simple preventive this one-time dread disease seems to have lost many of its terrors.

The Relationship of the Neuron to Disease of the Nervous System.—Dr. Lewellys F. Barker, who is well known by his recent treatise as an able and consistent expounder of the neuron-doctrine, read an interesting paper on this subject at the last meeting of the American Neurological Association (*Journal of Nervous and Mental Diseases*, September, 1900). The essential feature in this doctrine is the belief in the existence in the nervous system of definite nerve-units. This opinion is based especially on the work of Cajal, whose views have been accepted in large part by such eminent authorities as Kölliker, von Lenhossék and van Gehuchten, and confirmed by a host of competent observers. In Barker's judgment this doctrine is nothing more nor less than the application in full of the cell-doctrine to the nervous system. These nerve-units are complete nerve-cells, and the term "neuron" is intended to include not only the cell-body but also its processes. It abolishes, in brief, the old conception of a tissue or true network of nerve-fibers as distinct from the cell-body. There is no such network of fibers, but only an interlacing, as it were, of the processes (axis-cylinders, etc.) of the independent neurons. In other words, the "neuron" includes both the cell-body and all its processes. This conception is vital to an understanding of the doctrine.

This conception, however, in what may be called its primitive simplicity, has to be modified somewhat in view of later investigations. It is now considered probable, or even claimed by some to be demonstrable, that these cell-units or neurons do not remain absolutely distinct or dissociated, but that they are united to some extent by protoplasmic processes and delicate nerve-fibrils. The name of Apáthy is especially associated with this modification of the neuron doctrine. Barker evidently accepts the conclusions of Apáthy, for he says that they represent the most important discovery in neurological anatomy in recent years. He is quick, however, to claim that Apáthy's views do not in any way conflict with the neuron doctrine. This conclusion of Barker, however, does not quite accord with Apáthy's own words, which he quotes; for the latter distinctly repudiates the idea that the neurons are isolated units either in an anatomical or in a functional sense. He evidently bases this opinion on the anastomoses of his neuro-fibrils, which anastomoses, if words mean anything, constitute a reticulum or "continuum," which is practically identical in concept with the nerve network of the older anatomists. For Apáthy the body of a ganglion-cell is merely the center for "trophic and other regulatory influence of each definite domain." While this language does not convey a very precise

meaning it certainly seems to indicate for the nervous system a structure very similar to what was formerly believed to characterize it.

Dr. Barker's paper is especially valuable as embodying an attempt to harmonize these two apparently opposing conceptions of the nervous system, and as such it should receive from all neurologists a closer study than we can give it here. His views accord with those of Edinger, who believes that all the pathological relations of the ganglion-cell and its processes can only be explained by the neuron theory, and that this conception is not disturbed by the newly-won pictures of anastomosing fibrils. The truth seems to be that neuro-histologists are today arguing this question somewhat along the lines of their individual preferences, which are largely in favor of the neuron doctrine, and that Apáthy's views of anastomosing neurofibrils, while in a measure accepted reluctantly, are not yet fully harmonized with this doctrine.

Precautions of the United States Government Against the Plague.—Dr. H. D. Geddings, Acting Director of the Hygienic Laboratory of the United States Marine-Hospital Service, has recently published in the *Health Reports* an interesting paper in which he describes the methods adopted by the Government to provide against an outbreak of the plague. Dr. Geddings first reviews the subject of the antipest-serum and Haffkine's prophylactic, and goes over the ground recently covered in Dr. Rosenau's translation of Dr. Calmette's paper. As an editorial comment on that paper has just appeared in the JOURNAL, it is not necessary to review this portion of Dr. Geddings' article. We wish, however, to call attention to the fact, as described by Dr. Geddings, that the United States Government is taking every precaution to be well-armed. In the Hygienic Laboratory the preparation of a prophylactic fluid has been undertaken on a large scale. The modification of Haffkine's method, as recommended by the Pasteur Institute of Paris, was first tried. This consisted in a cultivation of the *Bacillus pestis* in agar-agar spread over large surfaces, and rendered as virulent as possible by special methods. The bacilli were then killed in the usual way by exposure to a temperature of 70° C. for several hours. It was found, however, that the chances for extrinsic contamination were too great by this method, and the technic has consequently been slightly modified. In order to avoid the growth of molds or ordinary air-organisms, especially the hay-bacillus, the plan has been adopted of growing the cultures in ordinary bouillon in flasks exposing a large surface to the air. By this method abundant crops of the organism are secured, and the risks of contamination are avoided. Each lot is tested to make sure that the plague-bacilli are killed by the heat, and some lots have also been tested on rabbits or other animals, both for innocuous-

ness and for efficiency. Large quantities of the fluid have been made and distributed to quarantine officers, national, state, and local, in the United States. Some of the fluid was used in the outbreak of plague in Honolulu, and more recently in the inoculation of about 600 persons in San Francisco. Altogether about 400,000 doses of 1 cc. each have been manufactured, and either distributed or kept on hand. This dose was determined upon as the standard, in preference to the larger doses of Haffkine, in view of the proved potency of the cultures. It is gratifying thus to note that the United States Government is thoroughly preparing itself for any emergency.

Nasopharyngeal Adenoids and Ear Disease.—Haight (*Transactions International Otological Congress*, August, 1899) says that adenoid growths are found in varying degrees of frequency in at least 3 parts of the world, viz., Europe, America, and Asia. He says nasopharyngeal vegetations are a hypertrophy of the lymphoid tissue forming a mass situated in the vault of the pharynx bounded on either side by the orifice of the eustachian tube. The author believes that the main factor in producing both suppurative and non-suppurative inflammatory conditions of the tympanic mucous membrane is the presence of these adenoid growths, or the condition of the postnares subsequent to their removal or absorption. They produce inflammation of the middle ear (1) by irritation on account of obstruction to the circulation of the blood by pressure; (2) by blocking the orifices of the eustachian tube; (3) by injurious effect upon the general economy of the child and particularly upon the nerves of special sense; (4) by having as a sequel a postnasal catarrh. Mouth-breathing is a prominent symptom of adenoids. Alderton is quoted as saying that in his opinion 35 to 88% of cases of middle-ear disease is due to adenoids. The author is of opinion that this affection causes many cases of deaf-mutism, and that it is a strong etiologic factor in causing imperfect mental development among those classed as feeble-minded children, and who by a trifling operation could often be restored to the normal condition. As a means of treatment he prefers the curet to all others, and that children above the age of 12 should have applied a local anesthetic only. In case a general anesthetic is given he prefers ethyl bromid. [A.B.C.]

Indications for Opening the Mastoid Abscess in Purulent Otitis Media.—Macewen (*Transactions International Otological Congress*, August, 1899) believes the mastoid should be opened: 1. In all cases of long-standing purulent otitis media, even though the patient is but little annoyed, because the danger of further complications is great. 2. In such cases as have lesions in the middle ear, which, though they could be removed by way of the external ear, can be removed with greater safety by way of the mastoid. Removal by way of the external ear is very apt to rekindle a smoldering point of infection. This applies particularly to so-called "aural polypi." 3. For the removal of necrotic bone, this being the only way the germs of infection can be eradicated. 4. Recurrent cases of purulent otitis media should be treated by this operation, and thus the danger of future complications be avoided. 5. Cholesteatoma and tuberculous processes with secondary pyogenic involvement should be treated by opening the mastoid, for only in this way can the diseased tissue be removed. 6. The author likens purulent otitis media to appendicitis, and says an early and complete operation is the best procedure in either case. It is the only procedure in which there is safety. 7. It may be necessary to open the mastoid to identify the suppurative organisms, in order to determine the character of the disease. 8. Opening of the mastoid should always be done as a preliminary step to any operation upon an intracranial lesion having its origin in purulent otitis media, abscess of the brain, of cerebellum, and sigmoid sinus thrombosis. 9. It is the safest and surest way of eradicating persistent purulent otitis media. [A.B.C.]

Correspondence.

CONGENITAL DEFORMITY IN TWIN BIRTH.

By ROBERT T. GLENDENNING,

of Manchester-by-the-Sea, Mass.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I WAS called, August 2, 1900, to attend in confinement a woman, 37 years of age, who had had 5 children, all girls. She had had an abortion at about 3 months just before becoming pregnant this last time. I had attended her with her last 2 children, the labor in both cases being quick and easy. On my arrival the pains were frequent and severe. On going to make an examination I found a portion of the amniotic sac between her thighs, containing quite a quantity of fluid. I punctured the sac, and making a vaginal examination, found quite a long piece of the cord coiled up in the vagina. I also found the mouth of the uterus well dilated and the buttocks presenting. The presenting part was so low down that all attempts at replacing the cord were unsuccessful. There was no pressure on the cord at this time, as the pulsations were 120 to the minute, full and strong. The pains came so fast that I did not make an examination of the abdomen. In a few minutes the buttocks were presenting at the perineum. Just before the child was born there was evidently considerable pressure on the cord, as the pulsations were reduced to 10 a minute. On delivery the child was somewhat asphyxiated, but soon began to breathe regularly. The child was a female, perfectly formed, but small, only weighing 4½ pounds.

After tying the cord the woman complained of having as severe pains as ever. I palpated the abdomen and found that there was a child in the uterus. On examination I found the feet presenting. After a vigorous pain the second child and placenta were delivered at the same time. The child was a female about the same size as the first child. It only lived about 15 minutes. The cause of death was a somewhat unusual congenital deformity. There was almost complete absence of the abdominal wall. The liver, stomach, and intestines were external to the body. The spleen was attached to the omentum at the base of the stomach. The amniotic sac was attached all around the abdominal opening. There was no true cord, but the bloodvessels from the placenta ran along in the amniotic sac to the upper border of the abdominal opening. The diaphragm was intact.

There was also a deformity of the left arm. The humerus was shorter than on the right. The forearm was at right angles to the arm and could not be extended on account of what appeared to be a contraction of the skin of the anterior surface of the elbow-joint.

RUBBER TAPE IN MINOR SURGICAL OPERATIONS.

By E. DREIFUS, M.D.,

of New Orleans, La.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I HAVE been recently making use of a new appliance in minor surgical work, and as I have not read of its use anywhere, thought it worth while reporting. It is the black rubber tape used by electricians for insulating joints or breaks whenever necessary in the course of their work. As nearly all of the simpler methods are discovered by accident, so this one was by me.

The first time I had occasion to use the tape was in the case of a young man who badly mashed an index finger while cleaning his bicycle. The finger was caught in the cogs of his wheel and terribly lacerated, the upper part of the phalanx looking like a mass of jelly. He came to my house with his hand wrapped up in a filthy blood-soaked handkerchief and complained bitterly of pain. I was just then occupied making some repairs to my electrical fan. I took off his dressing and at first sight made up my mind that the joint would have to be amputated. However, upon second consideration, I argued that I might try to save the joint and if my efforts proved unsuccessful I would always have time to cut. So I placed the finger in hot water and, as best I could, cleansed it of the oil and other foreign substances, and bathed it freely with pure hydrogen dioxid. Then the thought occurred to me that if I could keep the crushed parts in apposition, nature might be generous enough to repair the injury; and the tape being on my desk, it struck me to use it. The tape, I think, has some material in its composition that seems to be aseptic. I applied the tape, making a complete hood over the finger; a snug fitting bandage was then applied and the young man dismissed, and told to call in a week's time, unless he saw the bandage soiled, when he was to call. However, he did not call until the week expired. He said he had no pain at all after I dressed the finger, and, aside from the inconvenience of having his finger bandaged, he did not know he had a wound. I removed the dressing and to my astonishment the finger had completely healed. There had been no suppuration. This certainly was a gratifying result.

The next time I had occasion to use the tape was in the case of a little boy who fell against a curbstone while running, and cut a gash about 1½ inches long just along the superciliary ridge. He became so alarmed when he saw me thread a needle, preparatory to sewing the wound, that his mother begged me to try some other method. As the child was so frightened, and his mother so nervous, I concluded to try the black tape once more. I did so, bringing it completely around the head, making 3 rounds, and applied a roller bandage, instructing the mother to return in 4 days, with the child, which she did, and again I had the happy satisfaction of seeing the wound healed by first intention.

Since then I have used the tape in several cases in place of suturing, and I think it is an excellent substitute, especially with children and other highly nervous people. I do not know that I have added much to surgery by this little discovery, yet I believe we should all add our mite, be it great or small, towards alleviating pain and suffering.

POST-GRADUATE MEDICAL WORK IN BERLIN.

By J. R. CARE, M.D.,

of Norristown, Pa.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

MY first advice to those not familiar with the language would be to gain a thorough knowledge of the German tongue before going abroad. First, because the best post-graduate work is to be found in the German cities. Second, the ability to comprehend and speak the language is absolutely essential to grasp the advantages offered. So many, in considering work abroad, fail to realize this necessity, and spend months at a disadvantage in acquiring the tongue before any real medical work can begin.

All lectures and demonstrations are given in German, all textbooks and papers are in the German, and all intercourse with the people must be in the same language.

Since there are no medical bureaus in the German cities similar to the one found in Paris, I would advise anyone going there to secure a medical directory, which can be found at any medical book store in any of the larger cities. In this will be given a map wherein the location of all hospitals is specifically marked; also a catalog of the various courses presented.

The Charité Hospital in Berlin, which is the largest and oldest in the city, contains 1,300 beds; also numerous amphitheaters, which could scarcely be called modern, in which many of the lectures of the University course are given.

The most satisfactory work developed in this hospital is that of internal medicine. Another hospital of distinction is the Moabit, which occupies an entire block of the city, and was originally built as an emergency hospital during an epidemic of smallpox in the army.

Each ward is a separate and distinct building, one story high. Adjoining this hospital is the City Morgue, presided over by Professor Langerhans, who gives a most excellent course on pathology, histology, and postmortem technic.

At Friedrichsheim, a suburban section of Berlin, is situated a magnificent modern hospital, built on the pavilion system, and surrounded by beautiful grounds, which, in their decorations, display the superior landscape-art of the Germans, so strikingly noticeable throughout the German cities.

A very well-conducted hospital, where good general surgery may be seen, is St. Hedwig's, which is centrally located. Here one of the best general surgeons of the city, Dr. Rodder, operates 3 days weekly.

The Frauen Klinik, presided over by Professor Olshausen, who is one of the most expert operators in gynecology, presents splendid opportunities for that line of work. His assistants, Gebhard and Rhugi, give one of the best courses in gynecologic pathology to be found on the Continent.

Among the private hospitals I think Martin's is the best for Americans interested in gynecology. This is conducted by Professor Ortmann, who gives a very satisfactory course, demonstrated with abundance of material.

Professor Landau's Hospital, which is also a most excellent institution, is remarkable for vaginal work, as the Professor is the leading exponent of that method in Berlin. It was my fortune to have seen him perform numerous hysterectomies without the use of a single ligature. Dr. Thurman, an assistant to Dr. Landau, gives an excellent course on cystoscopy.

Berlin is a beautiful city, and quite the ideal place in which to spend a summer. One can live there comfortably on from 200 to 400 marks per month. Instruction costs from 40 to 75 marks per course. The great objection found is the wide distribution of the hospitals throughout the city. Hence one can accomplish less here in a limited time than in other cities on the continent. The Germans excel in diagnosis and pathology, but in surgical technic their work is inferior to that done in America. During operations their patients are less carefully guarded, and their open amphitheaters, with a few exceptions, are inferior to our operating-rooms.

FACIAL PARALYSIS FOLLOWING LA GRIPPE.

By JOHN C. BUCHER, M.D.,

of Lebanon, Pa.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

I HAVE had two cases of la grippe, with facial paralysis complicating, which struck me as being quite out of the ordinary. I consulted several authorities on the subject, and they make no mention of this complication.

Last February I was consulted by a man of 50 years, who came to my office with a well-developed attack of la grippe. He was suffering with a severe frontal headache, pains in his arms and legs, very chilly, with high fever, his temperature being over 103°; nasal passages slightly affected, but no

cough; his eyes reddened. I advised him to take his bed at once, that I would see him the next day, and gave him 4 grains acetanilid with $\frac{1}{32}$ grain strychnin every 2 hours. The next day, calling at his home, I found him greatly relieved, but he would not stay in bed; said he felt so much better, I need not come again. Two days afterwards, he left the house, and attended to his work—that of a teamster. For 2 or 3 days, he felt good, though weak, when he noticed that he could not expectorate as before, the saliva dropping on his chin and bosom; he also had a queer feeling in his forehead, but no pain. Coming to my office to report these facts, I at once noticed the peculiar condition of his face. The left side of his forehead was tightly drawn, the eyelids drooping, the eye itself being bloodshot; the corner of his mouth also drooping, and no wrinkles on that side. The right side of the face was perfectly normal. The wrinkles on the right side of his face were those of a man of his age, but they stopped in the center of his face, and the left side was perfectly smooth. The tongue was only slightly affected. The sensory nerves were not affected. The rest of the body was perfectly normal, appetite poor, bowels regular, bladder all right, no paralysis in his arms or legs. I gave him iron and strychnin with quinin, and he slowly improved, though he would not quit driving the team. The paralysis gradually disappeared, though it was the middle of April before it was no longer noticed.

The other case was not as pronounced, as it affected the right eye only. He was a stonemason, who had all the symptoms of la grippe; but his wife took charge of him, put him to bed, and gave him a good sweating, which relieved him of his chill and pains. Not content with leaving well enough alone, he started to work, and had the satisfaction of having the right eye turned inward to a remarkable degree. He then came to me for treatment. His general condition was good, said he felt strong. I could find no other cause for his condition except as a sequel of la grippe. With the tonic mixture of iron, quinin, and strychnin, his eye gradually assumed its normal condition.

Whether these conditions are common, I cannot say, as they are the only two cases which came under my observation. They both yielded readily to treatment; neither of them had any recurrence of the paralysis.

PSEUDO-MENSTRUATION.

By PAUL F. MUNDÉ, M.D.,

of New York.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

AT the time the second case of so-called "precocious menstruation" was reported in your issue of July 7, I had it in mind to write you correcting the misnomer, since it was perfectly evident that a discharge of blood for a few days from the genitals of a newborn female child did not constitute menstruation, "precocious" or otherwise. I marvel that either of the two gentlemen who reported the two cases could have so considered or termed it.

Having done my share in my professional life of medical writing, I then refrained from sending you a note on the subject. But I am pleased to see that some one else has recognized the error, and has taken the trouble to correct it. Your correspondent of August 16, however, while objecting to the term of "precocious menstruation" given to this slight postnatal genital hemorrhage, errs, I think, in ascribing the cause of the bleeding in such cases, as in the two reported by himself, to some constitutional dyscrasia inherited from the mother, tuberculosis, or, preferably, purpura hemorrhagica.

There is apparently no evidence whatever upon which to base such a supposition, for there is no mention made that the children were in any respect unhealthy; and to produce a genital or any hemorrhage which lasted a week, a tuberculous or purpuric dyscrasia would need to be so well marked

as to render the child anemic, emaciated, or, in the case of purpura, covered more or less with hemorrhagic petechiae. A cut surface, like the umbilical cord, might bleed under such a condition of the blood, but there is no cut or raw surface in the normal genitalia of a newborn female child.

Such temporary, slight, postnatal genital bleeding in girls is not rare. I saw it a number of times when interne at a maternity hospital in my youth. It was then attributed to compression of the pelvis during birth, as in breech presentations, or in large children where the breech (after coming) had to be extracted by traction. A rupture of a superficial bloodvessel in the vagina or cervical cavity might easily account for the trifling bloody oozing, especially if there is a catarrhal congestion of the cervical mucosa as is found in some newborn uteri. But the question is whether the supposed "bloody" discharge was really blood, and not urine discolored by a dark-red ("brick-dust") deposit, such as is quite common for a few days in newborn children of both sexes. This red urine would color the diapers precisely like blood, and could, on superficial examination, be readily mistaken for it. The "brick-dust" deposit takes place in the kidneys, from what cause and exactly how I do not now recall, being where I have no literature to consult on the subject—and is gradually washed down by the urine until in a few days it has all been eliminated. Only a microscopical examination could decide whether the red stain on the diaper was blood or urinary salts. If the latter, it had no special significance, and whether blood or salts the discharge is no more "precocious menstruation" than is the acute swelling of the breasts in newborn infants of either sex a puerperal mastitis.

HAY-FEVER AND CODLIVER OIL.

By S. SOLIS COHEN, M.D.,
of Philadelphia.

To the Editor of THE PHILADELPHIA MEDICAL JOURNAL:—

THE appended note from a careful observer who has had hay-fever 30 years or more may be of interest. In my own practice I continue to use the remedy I had the honor first to bring to professional attention in your columns two years ago—namely suprarenal extract, locally and internally. Conjoined in some cases with the use of oily sprays and the occasional administration of atropin or hyoscin hydrobromate in very minute doses, it gives almost complete relief temporarily.

My Dear Doctor:—I am able now to say that codliver oil used as a spray for the nostrils is a great palliative of hay-fever in my case. On days when there is a sea-breeze here the relief is almost total; on bad land-breeze days the relief is as great as heretofore obtained with other remedies on the best sea-breeze days, roughly speaking, about one half. I recommend the subject to the attention of the profession. The atomizer used is a hard-rubber oil atomizer. The oil is "deodorized." I use it once every 3 hours or oftener if required.

Internal Hemorrhoids.—Mathews (*Medical Age*, September 10, 1900) prefers the ligature to all other methods of operation for internal piles, because of its ease and simplicity, requiring fewer assistants than the clamp and cautery method. No matter how large the mass nor how large the separate hemorrhoidal tumors, he removes all at one sitting. He has seldom seen contraction follow. Should it do so, he advises simply opening the anus as if for examination, introducing a dilator, and dilating the stricture. Patients are generally completely recovered in from 10 days to 2 weeks. [G.C.C.H.]

American News and Notes.

PHILADELPHIA, PENNSYLVANIA, ETC.

Dr. Hu King Eng, physician to the Empress of China, graduated from the Woman's Medical College of Philadelphia.

The Schuylkill County Medical Society met at Pottsville, September 11. Dr. W. C. J. Smith, of St. Clair, presided at the convention.

Adulterated Milk.—William J. Reilly was tried in a Philadelphia Court recently for selling adulterated milk. The chemist of the Board of Health found that one quart of water had been added to 6 quarts of milk.

Oleo Dealers Fined and Sentenced.—Last week 5 Philadelphia dealers were fined \$100 each for the illegal sale of oleomargarine, and 4 of these also received from 10 to 30 days in the county prison. Another dealer pleaded guilty to selling adulterated mincemeat and was fined \$50.

The Sanitarium Association of Philadelphia has just completed its twenty-fourth year. During the last year 6,189 more admissions were recorded than during any previous year. During 73 working days there were 180,670 admissions. The baths were enjoyed by 23,265 boys, 25,591 girls, and 4,516 infants and 82 mothers were admitted to the hospital with sick children.

Faith Curists Indicted.—An indictment has been preferred against Harry E. Sollenberger and Ezra Sheets, of Philadelphia, charging them with the murder of a 7-months-old infant, left in their charge at the "Beulah Orphanage" or "Fire Baptized Holiness Mission," conducted by them. The little one became ill and they failed to procure medical attention, with the result that the infant died.

Contagious Disease Ward Needed.—The medical profession of Philadelphia is much concerned at present in the maintenance of a contagious disease ward at some of the city hospitals, where people of the working class able to pay a little can send their children. The matter will in all probability be urged before the next meeting of the Board of Charities and an appropriation for such work asked.

Bequests to Charity.—By the will of the late Samuel W. Brown, of Manayunk, Pa., the Home for Aged Couples of the Presbyterian Church received \$5,000. Legacies of \$2,000 are left to each of the following institutions: Northern Home for Friendless Children, Southern Home for Destitute Children, Old Men's Home, Society to Protect Children from Cruelty, and Children's Aid Society. Part of the residuary estate is left to the Presbyterian Home for Widows and Single Women. Howard Roberts, of Bryn Mawr, left a legacy of \$10,000 to the Pennsylvania Hospital.

Board of Charities.—At a recent meeting of the Philadelphia Board of Charities and Correction a communication from the Mayor was received which contained several recommendations. Among these was a centralization of authority, or condensation of method and work, making the superintendent take the place of the Board. This feature was not favorably received. In the interest of economy the Mayor recommended the consolidation of the office at 42 North Seventh st. with the Philadelphia Hospital. Also that there be a reduction in the number of salaried men. In the matter of selecting the medical staff, resident and visiting, he expressed the wish that the 3 great medical colleges be equally represented by the best medical and surgical skill. He urged the construction of a new insane department in an outlying section of the city, and said he had in view the taking of a large tract of land, which could be used jointly with the development of the new water system. A motion was passed that the Board have a full consultation with the Mayor on the subjects covered by the communication. The following vacancies were reported: Treasurer of the Board, chief druggist, electrician, pathologist, laryngologist and register of the Philadelphia Hospital, physician of the insane department, secretary of the Bureau of Charities, and captain of the guard at House of Correction.

The Company Doctor.—One of the demands of the coal miners in the Pennsylvania anthracite regions, says a local paper, is that each man shall be permitted to engage for himself and his family a doctor of his choice. It is stated that at present the men are compelled to accept the services of the "company doctor." John B. Garrett, vice-president of the Lehigh Valley Coal Company, recently made this statement: "This company employs no doctors and makes no charges against its employes for medical service to them or their families. Inquiry has satisfied me that this is also the case with the companies generally, and that the company doctor is charged for only by individual operators, and by very few of these."

Hospital for Tuberculous Patients.—Some years ago the general hospitals of Philadelphia closed their doors to tuberculous patients who could not pay enough to warrant the maintenance of a separate ward. This made the lot of the poor victims of the disease who were in need of care very hard, and induced Dr. Lawrence F. Flick and others to organize the Free Hospital for Poor Consumptives in this city, in 1895. There is no hospital building in the control of the society, but the patients who apply to it are sent to the general or special hospitals under pay. In the first year 40 patients were provided for, at a cost of \$1,912; last year 124 were kept in the hospitals, at a cost of \$6,118. During the first 6 months of this year 116 patients have been cared for, at a cost of \$4,585. There is every reason to expect a steady increase in the number of patients as the resources of the society grow, and it is hoped in time to build a new institution especially for poor tuberculous individuals.

Vital Statistics of Philadelphia for the week ended September 15, 1900:

Total mortality		420	
Disease.	Cases.	Deaths.	
Inflammation of appendix 5, bladder 3, brain 12, bronchi 1, kidneys 19, larynx 1, liver 1, lungs 19, heart 2, peritoneum 9, stomach and bowels 25, spine 1		98	
Tuberculosis of the lungs		51	
Marasmus 24, inanition 20, debility 4		48	
Heart-disease of 25, fatty degeneration of 2		30	
Cholera infantum		24	
Convulsions 18, puerperal 1		19	
Uremia 11, Bright's disease 7, diabetes 1		19	
Apoplexy 8, paralysis 10		18	
Carcinoma of bladder 1, breast 2, face 1, liver 3, rectum 1, stomach 6, uterus 2, tumor 2		18	
Diphtheria	81	15	
Typhoid fever	63	10	
Casualties		10	
Burns and scalds		5	
Diarrhea		5	
Brain—disease of 1, softening of 3, congestion of 1		5	
Old age		4	
Suicide—hanging 1, gas 1, shooting 1		3	
Teething		3	
Septicemia		3	
Scarlet fever	30	1	
Psoas abscess 1, alcoholism 1, asthma 2, anemia 1, atheroma 1, childbirth 1, cirrhosis of liver 2, membranous croup 1, drowned 1, epilepsy 1, puerperal fever 1, gallstones 1, homicide 1, measles 2, locomotor ataxia 1, obstruction of the bowels 2, opium poisoning 1, arterial sclerosis 2, surgical shock 1, suffocation 1, sunstroke 1, syphilis 2, tetanus 1, ulceration of stomach 1, whooping-cough 1			

NEW YORK.

Fire in Hospital Morgue.—Fire in the morgue of Roosevelt Hospital, recently, caused by the explosion of a plumber's benzine lamp, did \$500 damage before it was extinguished. There were no bodies in the building at the time.

Inspection of Schools.—The health and education authorities of Paterson, N. J., are considering a proposition to have a physician make a daily inspection of the children in the public schools, so that if any of them have ailments of any kind they can be promptly treated. This experiment has been tried in the Asbury Park schools and proved a great success.

Typhoid in Women's Hospital in Syracuse.—An epidemic of typhoid fever has broken out in the State Custodial Asylum for Feeble-minded Women at Syracuse and 12 persons are down with the fever, including the resident physician.

The public baths in New York have recently been inspected by the Board of Health. The Market Street bath has been removed and all the others have been declared pure, except the one at the foot of Duane Street which is pending a second investigation.

Baths Responsible for Conjunctivitis.—Dr. Carey, of the New York Eye and Ear Infirmary, has decided that the public baths along the rivers' front are responsible for an epidemic of conjunctivitis similar to the one in Brooklyn 2 weeks ago from the same cause. In one day 196 cases of the disorder were treated at the infirmary.

The Quarantine Inspection of Immigrants.—According to the annual reports of the quarantine and health officer of the port of New York for the year 1899, over 300,000 steerage passengers, arriving by the various steamship lines, were inspected during the year at the quarantine station. Some 4,658 passengers from "foreign" vessels were also inspected.—[*New York Medical Journal*.]

Four New Electric Ambulances.—According to the *Medical News*, automobile or electric ambulances are being built for private hospitals in New York. The Roosevelt, Presbyterian, and New York Hospitals are making the experiment. St. Vincent's Hospital has had an electric machine for several months. The vehicles for Roosevelt are 7 feet 6 inches long, which is about 18 inches longer than the ordinary horse-drawn ambulance, and weigh 4,800 pounds each.

Free Cremation.—New York physicians have recently been receiving from a certain cremation company a circular which reads as follows: This certifies that, in recognition of the support which our cause has received from physicians generally, ———, M.D., or any member of his immediate family, is hereby entitled to incineration without charge at our ——— crematory, upon proper indorsement and surrender of this certificate, within 10 years from date. (Kindly return this certificate if you do not wish to use it.)

The water-famine in Brooklyn has become a serious question. There seems to be no immediate remedy except rainfall. A big fire or an accident to the water-plant would at present have the most serious results. Chief Engineer Bardsall says relief in the remote future lies in the conduit from Spring Creek to Milburn which will cost \$1,000,000, the Milburn reservoir to cost \$500,000, and a pumping engine at Milburn to cost \$75,000. All three projects are in the Municipal Assembly.

New Hospital for Tuberculosis.—At its annual meeting, held at Albany, N. Y., recently, the Board of State Pensions passed a resolution adopting the report of Commissioner Mantanye, which recommends Dannemora (the location of one of the State prisons) as the site for the erection of the State Hospital for Tuberculous Individuals, and urging the Hospital Commission to act in favor of the recommendation. Dannemora is situated in the northern part of Clinton County, in the Adirondack region.—[*Boston Medical and Surgical Journal*.]

Free-Milk Giving Discontinued.—The free distribution of pasteurized milk which has been carried on since July 17 by the Brooklyn Bureau of Charities has been discontinued. There has been an average daily distribution of between 1,600 and 1,700 six-ounce bottles of pasteurized milk for children. The milk has been distributed from 7 different stations in the city upon the receipt of an order from a physician or from the district nurses connected with the Bureau of Charities. The funds were obtained in response to an appeal issued by the Bureau of Charities early in the summer. The entire cost will be somewhat less than \$2,500. Notwithstanding the unusually hot weather, the statistics in the office of the Board of Health show that the rate of infant mortality has been lower than for the same period during the 5 years preceding, and some of the result is attributed to the distribution of milk.

Thousands for Charity.—By the will of the late George D. Sweetser, of New York, the following bequests of \$5,000 each have been made to the following institutions: New York Skin and Cancer Hospital; New York Society for the Suppression of Vice; Society for the Relief of Ruptured and Crippled; New York Infant Asylum; House of Rest for Consumptives; Woman's Hospital; New York Christian Home for Intemperate Men; Sheltering Arms; Colored Home; Home for Incurables; Children's Aid Society; Howard Mission for Little Wanderers; and the Five Points House of Industry.

Stable Refuse and Health.—Contractors for the removal of stable refuse from Manhattan and the Bronx, N. Y., have been enjoined by Justice Bischoff of the Supreme Court from dumping manure opposite a hotel in Glenwood, and thereby creating a nuisance detrimental to health. Dr. E. Harrison Griffin testified that he had carefully observed the effect of gases arising from fermenting stable refuse upon the respiratory organs, and deemed them conducive to health, and he had advised patients suffering from catarrh to spend as much of their time as possible about horses, where they could inhale such gases and odors. The Justice in his decision says: "With the optimism to concede the benign effects of the effluvia, which but for the injunction must envelop the plaintiff's hotel, a sojourn in the place could be the result of choice only by persons deliberately seeking a cure, but such heroism cannot be looked for in the public at large, among whom the plaintiffs may rightfully seek their patrons under normal conditions."

Plague Germs to be Cultured.—The Board of Health of New York has prepared plans for a bacteriologic laboratory in which bubonic plague germs are to be cultured. It will be constructed of steel, with solid asphalt walls. There will be neither chimney nor windows. The lighting will be by electricity. The cost of the structure will be \$25,000. Two cases of plague have been treated at quarantine during the last year, and the city is totally unprepared to meet the emergency that would be occasioned by its appearance. Every precaution will be taken to safeguard the workers in the laboratory. Several deaths have occurred from plague among the laboratory workers in Lisbon and Vienna during the last 2 years. Having these fatalities in mind the Board of Health did not regard any bacteriologic work in relation to the plague as safe in the general laboratories throughout the city. The diagnosis and the treatment, preventive and curative, of plague rest almost entirely upon the result of bacteriologic investigation. It therefore becomes necessary that the facilities for carrying on such work shall be unexceptionable; and at present the department does not command such facilities.

The Buffalo Academy of Medicine—Section of Medicine.—At the regular meeting held September 11, Dr. A. L. BENEDICT read a paper entitled **Quantitative analysis of gastric proteid digestion**, in which he remarked that notwithstanding the extensive studies for the past ten years, of gastric digestion, none of the methods of chemic examination in common use deals directly with the prime function of that organ, *i. e.*, converting albumins into peptones. He touched upon the physiology of gastric digestion and divided that of albumin clinically into the production of: (1) Soluble acid albumin or syntonin, (2) albumose or propeptone, (3) peptones. His method of analysis depends upon the separation of the proteids into the three classes mentioned, by the estimation of the bulk of moist precipitates by the centrifuge. He states that the bulk varies enormously according to reagents used. His reagents are: for albumin, heat; for albumose, ammonium sulfate to saturation; for peptones, phosphomolybdic acid. His technic is to prepare the gastric contents for filtration by rapid cooling and centrifugation. He presented several tables the result of sixteen examinations of gastric contents after Ewald's test-breakfast, from healthy students, and concluded that (1) the proportions of the three stages of proteids do not vary materially during the third half hour of digestion, (2) syntonin is represented by a mere trace, (3) albumose by a mere trace, (4) peptone varying but in large quantity (he gives exact quantitative figures). He also presented tables from the examination of the gastric contents of a large number of pathological cases, but did not draw any conclusions from

them as groups of cases. He claims that in the use of this method of analysis the differences in the stages of digestion of the different animal and plant albumins assume relatively less importance as the various intermediate products are precipitated by ammonium sulfate, that the method does not require a long time, much apparatus nor many chemicals and that the results have a more even clinical value than the more refined but cumbersome methods. He states that as digestion once started in albumins is uninfluenced by the presence of undissolved masses of food and as ferments are almost inevitably present in abundance if free hydrochloric acid in reasonable amount be present after the preliminary one to one and a half hours, the liquid portions of the chyme are subjected to nearly the same conditions, whatever the bulk of the meal, its exact nature or the time after ingestion. It must be remembered, however, that the amount of an end-product of digestion depends upon two opposite factors, digestive activity and absorptive activity, hence it is difficult and often impossible to determine whether a large amount of end-product is due to good digestion or poor absorption, as no reliable test for absorption is known at present. He thinks that the titrating test of absorption is very unreliable because of the unknown values of (1) loss through the pylorus, (2) removal by absorption, and (3) the addition by secretion.

NEW ENGLAND.

A Charitable Bequest.—By the will of the late Charles H. Smith, of Providence, R. I., the Home for the Aged of Pawtucket received \$1,000.

Anthrax in New Haven.—Morris Sachs, of New Haven, Conn., died recently of anthrax. He had been buying hides in Long Island, where he contracted the disease.

Boston Public Baths.—All the public bathing places of Boston, Mass., except the Dover Street bath, are closed. Total number of bathers for June, July, and August, is 1,950,608. In 1899 the total was about 1,500,000.

Diphtheria in Brookline.—An epidemic of diphtheria prevails in Brookline, Mass., where 40 cases have been reported in the last 6 weeks. Some of the schools have been closed. Circulars recommending caution have been distributed by the Board of Health.

CHICAGO AND WESTERN STATES.

The National Wholesale Druggists' Association held its twenty-sixth annual meeting in Chicago last week.

The hospital-ship "Solace" has arrived at San Francisco from Yokohama, bringing 17 sick and wounded.

Ptomain Poisoning.—The family of William Swain, of Grand Crossing, Ill., is dangerously ill, due to ptomain poisoning caused by eating sardines.

"The Bacillus" is the name of a new monthly periodical published under the auspices of the Illinois Medical College. Dr. Fred. C. Zapffe is editor.

Physician Suffers from Hiccough.—Dr. H. A. Pick-erell, of Beverly, Kan., has been suffering for some time with hiccough. He has tried more than 30 remedies without avail.

Bids for Construction of Hospital.—Bids were opened recently for the construction and equipment of a 24-bed hospital at Fort Stevens, Ore. The lowest bid of \$25,194 will be accepted.

Home for Poor Girls.—Former Governor John S. Pillsbury and wife will build a home for poor girls at Minneapolis, Minn., and present the edifice, when completed, to the Woman's Christian Association.

The Forum of Tuberculosis, Climatology, and Hydrology will meet in Chicago, November, 1900, for the study and consideration of all matters relative to tuberculosis, and of the therapeutic effects of the various springs and mineral waters of the continent.

To Care for Pupils' Health.—It is reported that medical inspection of the Chicago schools is to be more thorough this year than ever before. Recently 50 medical inspectors were given instruction for their guidance.

Typhoid Fever and Milk.—An epidemic of typhoid fever has existed in the northern part of Milwaukee. Practically all the cases, 40 in number, occurred in the route of one milk dealer. A case of typhoid was found in his family.

Physician Becomes Insane.—Dr. W. C. Putnam, of Oconto Falls, Wis., has been committed to the insane hospital at Oshkosh. His derangement is said to have been caused by powerful drugs taken in an overdose when he was suffering from sickness.

Wants a Commission.—Rev. William H. Barnes has filed a suit against the St. Louis Baptist Hospital Association asking for commissions on donations that he claims to have secured for the association, and for pay for other services which he says that he has rendered, amounting in the aggregate to \$3,659.53.

Woman Physician Without Certificate.—Physicians in Calumet, Mich., object to a woman practitioner of that town who came there four months ago from Helsingfors, Finland. She says her ignorance of English prevents her from taking an examination, but she says she is a graduate of Helsingfors University.

State Hospitals of California.—It is reported that a change is to be made in the management of the State hospitals at Sacramento, Cal., by which Dr. F. W. Hatch, now superintendent of State hospitals, will be put in charge of the Napa Hospital as medical superintendent, to succeed Dr. M. Gardner, who will establish a private sanatorium.

Anthrax and Tuberculosis Among Cattle.—Tuberculosis has made its appearance among the cattle at the Jackson county poor farm near Black River Falls, Wis., and the State veterinarian has been there to look into the situation. He went to Millston and Warrens, where it is said cattle are afflicted with anthrax, which it is claimed is caused by the cattle drinking stagnant or impure water.

Rabies Among Horses and Cattle.—Rabies still continues near Decatur, Ill., and a large percentage of the livestock on farms in Illini and Harriestown townships seems to be affected. Dr. S. H. Swain insists that all the dogs in the two townships must be killed as the only means of safety for the people and livestock. So far hundreds of dollars' worth of cattle, horses and sheep have died. One case developed in the city recently, which would indicate that the disease is spreading.

SOUTHERN STATES.

Dr. H. A. West, of Galveston, whose death was recently announced by the Associated Press, is safe.

The Government Hospital Building at Savannah, Ga., which cost \$1,000,000, has just been sold for \$17,000.

Virginia Penitentiary.—It is understood that Dr. Charles V. Carrington, of Richmond, Va., will be appointed surgeon to the Virginia Penitentiary to succeed Dr. Benjamin Harrison, deceased.

Washington Asylum.—Dr. Percy Hickling has forwarded to the Commissioners of the District of Columbia the resignation of Dr. J. F. Wallace, the resident physician at the Washington Asylum, and recommends that Dr. O. Baker be appointed to fill the vacancy. It is understood that the recommendation will be approved.

Southern Medical College.—Dr. H. F. Harris, associate professor of pathology, Jefferson Medical College, Philadelphia, has been elected professor of pathology and bacteriology in the Southern Medical College, Atlanta, Ga. Dr. Harris assumes his new duties at the beginning of the present college year. His successor at the Jefferson Medical College has not been named.

Texas Quarantines San Francisco.—The State Health Officer of Texas still retains the quarantine against San Francisco, and intimates that it will now be more rigid than ever. El Paso merchants object to the measure.

Fined for not Reporting Smallpox.—Dr. A. L. Lopez, a negro physician of New Orleans, was recently, upon instigation of the New Orleans City Board of Health, fined \$25 for not reporting a case of smallpox under his care.

Quarantine Restrictions.—The *Adria*, a vessel loaded with fruit from Jamaica, arrived at New Orleans recently, but the Board of Health refused to allow the ship to come to the wharves, and it had to be unloaded on barges at the 9-mile point below the city.

Nurses for the Poor.—For the month of August the 3 nurses employed by the people of Washington, D. C., report 822 visits made on 165 patients, who would have been otherwise almost without care or attention. The work has been greatly helped by food and special diet provided by the Citizens' Relief Association and the Diet Kitchen.

Aid for Indigent Sick.—The Board of Charities of the District of Columbia recently made an allotment of \$7,920 for physicians to the poor, \$2,480 for medicine and nursing and \$500 for coffins to be used for the burial of the indigent dead. An allotment of \$400 was also made for the Woman's Dispensary. The present appropriation bill carries the sum of \$700,000 to be used in the board's schedule.

The Army Medical School, at Washington, D. C., is governed by special regulations, and will have the following organization: 1. The faculty, which will consist of four or more professors selected from the senior officers of the medical department stationed in or near the city of Washington and such associate professors as may be required. The senior officer will be president and the junior secretary of the faculty. 2. The student officers will be selected by the Surgeon-General from those medical officers who have been appointed since the last preceding term of the school and such others as may be authorized to attend.

To Care for Medical Students at Galveston.—The recent storm caused a loss of \$70,000 to the State University in Galveston. The medical branch of the institution was located there and the session was to have opened September 26. Steps will be taken to accommodate the students in some manner, and if it is found that they cannot be accommodated in Galveston, they will probably be given room in the main buildings of the university at Austin, temporarily. The Sealy Hospital survived the storm. The nurses' home was completely demolished, but there was no loss of life. There was no loss of life among the regular inmates of the hospital.

Dr. Hunter McQuire, who died at Richmond, Va., September 19, was one of the most eminent medical men of the South, and one of the best known in the United States. He had a stroke of paralysis six months ago. His career in the army of the Confederate States was distinguished for gallantry and humanity. He was chief-surgeon of the Stonewall Brigade, and a member of the staff of the Confederate general, by whom he was most highly regarded. He established the humane practice in both armies of releasing all medical officers who were captured. He was instructor of surgery at the Jefferson Medical College at the time of the John Brown raid, and, becoming offended at the comments regarding that affair, he organized a movement which resulted in all the Southern medical students in Philadelphia—at that time about 300—leaving the city and entering the Medical College of Virginia. The expenses of the transfer were met by the city of Richmond, though the money was advanced in the first place by Dr. McQuire himself. The students met at the college and marched in military formation to the depot, Dr. McQuire at their head. At the close of the war he was appointed to the chair of surgery in the Medical College of Virginia. He resigned in 1878, but in 1880 accepted the emeritus professorship of surgery. In 1877 he received the degree of LL.D. from the University of North Carolina, and in the following year a similar honor was conferred upon him by the Jefferson Medical College. In 1883 he established St. Luke's Hospital, and in 1894 he established the Virginia Hospital and the University College of Medicine.

MISCELLANY.

Our leper colony at Molokai contains 1,100 persons—625 males and 475 females. Of the entire number 954 are Hawaiians, 62 are half-breeds, 37 are Chinese, 5 American, 4 British, 4 German, and 6 Portuguese.—[*Medical Age*.]

Hospital Stewards.—The examination papers of candidates for promotion to the grade of hospital steward have been examined and the work will not be completed for 2 or 3 weeks. There are 15 places in this country and 20 in the Philippines.

To Prevent Plague in Hawaii.—Claims aggregating \$2,300,000 have arisen in connection with the efforts made, principally in Hawaii, to prevent bubonic plague from securing a foothold in this country and its outlying possessions, by burning down a large part of the Japanese and Chinese quarter at Honolulu, where it was thought the disease might find lodgment.

Yellow Fever in Havana.—In Havana 78 cases of yellow fever are now under observation. The mortality report for August, including deaths from all causes, shows a lower total than for any previous August in 10 years, the figures being 559 as against 620 in 1899 and 1,978 in 1898. The deaths for August were 276, yellow fever furnishing 49 victims and tuberculosis 65.

Instruction for the Deaf.—The number of pupils in schools for the deaf in the United States in 1899 was 10,291. Of these 61% are taught speech, oral instruction being used exclusively, or a "combined" method. The balance of 39% are not taught speech, but use the sign or manual methods exclusively. It is noticeable that the oral method predominates most strongly in the New England or Middle States. In the Central and Western States 53% are taught speech, while in the Southern States only 31% are under oral instruction.

Rates of Hospital Charges.—General Miles has issued an order prescribing the following rates of hospital charges: For subsistence of a retired enlisted man, 40 cents per day; for nursing, medicines, and subsistence of a civilian employe, 40 cents per day; for officers of the army, seamen, and river boatmen (admitted only on permit issued by a medical officer of the Marine-Hospital Service or a customs officer), and civilians admitted as provided in the preceding paragraph, \$1 per day. The money received will be accounted for with the hospital fund.

Distress in Alaska.—The Secretary of the Treasury has received a dispatch from Alaska, stating that a most deplorable condition exists among the native Indians along the coast from Cape Nome northward. The Treasury officials are powerless to render aid to the sufferers because the department has no available funds, but the War Department has a fund that can be drawn on in emergency cases like the present. The Treasury Department will furnish surgeons from the Marine-Hospital Service, and the Custom-officers will be instructed to render any assistance possible.

Obituary.—E. S. ARMSTRONG, of Perry, Ralls County, Mo., September 8.—B. F. BUFFEN, of Bay City, Ore., September 6, aged 74.—CORTLANDT VAN RENSSLAER HODGE, in China, formerly of Philadelphia, aged 28.—JOHN MCMAHON BROWN, of New York, September 12, aged 55.—W. E. BRONTE, of Brinkley, Ark., September 11.—WILLIAM S. BROWN, of Baltimore, September 7.—BENJAMIN HARRISON, at Millwood, Va., September 10.—WILLIAM A. HILLEBRECHT, of Hackensack, N. Y., September 8, aged 26.—DENNIS DOWLING MULCAHEY, of Newark, N. J., September 11, aged 52.—FRANK W. MERRIAM, of Waterford, Conn., September 16, aged 46.—W. SCOTT WOLFORD, of Philadelphia, September 18, aged 53.

Smallpox.—The health authorities of Kansas City are concerned over the prospect of a serious outbreak of smallpox this winter, and are beginning to take elaborate precautionary measures. Last winter there was almost an epidemic, which cost the city \$65,000 to suppress. The disease was not entirely stamped out during the summer, and it now seems to be on the increase again. Several cases are also reported from Lake Linden and the copper district of Michigan and 3 from Winfield, W. Va. Two new cases have been discovered in New Bedford, Mass.. At the quarantine

station of that place all are reported doing nicely and on September 15, 16 cases were discharged as cured. The Board of Health has ordered another delay in the opening of the North end schools. Because of a case of smallpox on board, the steamer *Walla Walla* is quarantined at William's Head, and is liable to remain there for 2 or 3 weeks with her crew and passengers in confinement. The Pacific Mail Company's steamer *Neuport* will also remain in quarantine at San Francisco for several days. A case of smallpox developed while she was on her way to that port.

Health-Reports.—The following cases of smallpox, yellow fever, cholera, and plague have been reported to the Surgeon-General of the U. S. Marine-Hospital Service, during the week ended September 15, 1900:

SMALLPOX—UNITED STATES.				CASES.	DEATHS.
ALASKA:	Nome	Aug. 18		3	
COLORADO:	Jefferson Co.	Aug. 23—Sept. 1		11	
"	Las Animas Co.	Aug. 23—Sept. 1		1	
KANSAS:	Wichita	Sept. 1-8		1	
LOUISIANA:	New Orleans	Sept. 1-8		2	
MINNESOTA:	Minneapolis	Sept. 1-8		1	
"	Winona	Aug. 23—Sept. 4		3	
OHIO:	Cleveland	Sept. 1-8		2	
"	Dayton	Sept. 1-8		1	
TEXAS:	Eagle Pass, in Mexican portion of town.	Sept. 7		1	
UTAH:	Ogden	Aug. 1-31		2	
"	Salt Lake City	Sept. 1-8		1	
WEST VIRGINIA:	Wheeling	Sept. 1-8		1	

SMALLPOX—FOREIGN.				CASES.	DEATHS.
AUSTRIA:	Prague	Aug. 18-25		2	
BELGIUM:	Antwerp	Aug. 18-25		1	
BRAZIL:	Rio de Janeiro	July 13-30		38	10
ENGLAND:	Liverpool	Aug. 18-25		6	
"	London	Aug. 18-25		1	
INDIA:	Bombay	Aug. 1-14		6	
"	Calcutta	Aug. 4-11		7	
"	Karachi	Aug. 5-12		1	1
MEXICO:	City of Mexico	Aug. 26—Sept. 2		4	5
RUSSIA:	Moscow	Aug. 11-18		6	
"	Odessa	Aug. 18-25		1	
"	St. Petersburg	Aug. 11-25		96	11
"	Warsaw	Aug. 11-18		10	
SWITZERLAND:	Zürich	Aug. 11-18		1	

YELLOW FEVER.				CASES.	DEATHS.
BRAZIL:	Rio de Janeiro	July 13-20		10	
COLOMBIA:	Barranquilla	Aug. 19-26		1	
"	Panama	Aug. 27—Sept. 1		3	1
CUBA:	Cienfuegos	Sept. 8		1	
"	Havana	Aug. 2-26		215	34
"	"	Aug. 26—Sept. 1			23

CHOLERA.				CASES.	DEATHS.
INDIA:	Bombay	Aug. 1-14		693	
"	Calcutta	Aug. 4-11		35	

PLAGUE.				CASES.	DEATHS.
INDIA:	Bombay	Aug. 1-14		105	
"	Calcutta	Aug. 4-11		52	
PHILIPPINES:	Cebu	July 14-21		1	
"	Manila	July 14-21		4	
TURKEY:	Constantinople	Aug. 27		1	On S. S. "Niger," from coast of Asia Minor.

The Pan-American Congress.—An announcement of the coming meeting of the Pan-American Congress in Havana, Cuba, has been received from the secretary, Dr. Tomas V. Coronado, of Havana. Dr. Coronado says: "Counting on your love for, and devotion to, professional matters I would be extremely pleased if you would favor us with your personal assistance and also by interesting your medical societies, universities, or medical schools, as well as your prominent colleagues who are teaching the medical sciences, so that they will take part in the Congress which convenes on December 26, 27, 28, and 29, 1900, and will send delegations, the members of which should forward their papers, or the titles.

"Our climate, our soil, and the grade of civilization itself to which we have arrived produce appreciable modifications in the diseased conditions that develop in an atmosphere so

distinct from that of Europe, and the diseases belonging to these latitudes the study of which is being perfected each day, are sufficient motives to authorize the scientific investigations of our Congress.

"In these controversies the combined efforts do not represent the sum of the units that compose them, but represent the multiplication of them. The simultaneous work of all the investigators of the Americas presented and discussed at a given time surely must produce surprising results in reference to the utility and the practical application of the scientific production of the men who cultivate successfully the medical sciences on the American continent. I sincerely hope that our sister nation whose medical attainments are so famous, will cooperate in promoting the success of the Third Pan-American Congress by sending the largest possible representation, both in delegates and scientific production." The members of the Congress consist of physicians of the Western Hemisphere, including the West Indies and Hawaii, that comply with the special regulations of registration, and the board of executive officers are selected, formed from the residents of the country in which the Congress is held. The official languages of the Congress will be English, French, Spanish, and Portuguese.

Changes in the Medical Corps of the U. S. Army for the week ended September 15, 1900:

GOULDING, TIMOTHY F., acting assistant surgeon, upon completion of the duties required in connection with the abandonment of the post of Cardenas Barracks, will proceed to Rowell Barracks, Paso Caballos, for duty.

SUMMERALL, WILLIAM B., acting assistant surgeon, is granted leave for 1 month, with permission to go beyond the limits of the division of Cuba.

HOFF, Major JOHN VAN R., surgeon, will proceed to Nagasaki, Japan, on the mail steamer "Hong Kong Maru," to sail August 29. Upon arrival at Nagasaki, Major Hoff will report to the depot quartermaster for transportation to Taku, China.

KNEEDLER, HARRY D., acting assistant surgeon, is relieved from duty with Siege Battery O, Seventh Artillery, now at the Presidio, and will report to the commanding officer, Light Battery C, Seventh Artillery, now at that post, for duty with that battery.

McLAUCHLIN, WHARTON B., acting assistant surgeon, is relieved from temporary duty at the Army General Hospital, Presidio, and will report to the commanding officer, First Battalion, Fifth Infantry, now in camp at that station, for duty with that battalion.

STARK, Captain ALEXANDER N., assistant surgeon, is granted leave for 1 month and 15 days, with permission to go beyond the division of Cuba.

ROBERTS, WILLIAM, acting assistant surgeon, is relieved from temporary duty at the Army General Hospital, Presidio, and will upon arrival in San Francisco, Cal., of the Second Battalion, First Infantry, report for duty with that battalion.

PRENNELL, JAMES F., acting assistant surgeon, will stand relieved from further duty with the Second Battalion, First Infantry, upon its arrival in San Francisco, Cal., and will proceed to Alcatraz Island for temporary duty at that post, to relieve Acting Assistant Surgeon Aubrey F. Higgins.

HIGGINS, AUBREY F., acting assistant surgeon, will proceed to his home, Germantown, Pa., where he will report by letter to the Surgeon-General of the Army, for annulment of contract.

LYSTER, WM. J., acting assistant surgeon, is granted leave for 1 month, from September 1.

ASHBURN, First Lieutenant PREY M., assistant surgeon, is granted leave until September 30.

LITTLE, WILLIAM L., acting assistant surgeon, is assigned to temporary duty at Fort Sam Houston, pending the departure of Companies C and D, Twenty-fifth Infantry, for duty in the division of the Philippines.

GOMEYS, Major EDWARD T., surgeon, orders of August 15 directing him to proceed to Nagasaki, Japan, for duty as medical supply officer at that place, is amended so as to direct him to proceed to Taku, China, with all medical supplies invoiced to him, and establish medical supply depot at such points as may be designated by Major-General Adna R. Chaffee.

KIRKPATRICK, First Lieutenant THOMAS J., assistant surgeon, leave granted him for 7 days, September 1, is extended 7 days.

PHILLIPS, Captain JOHN L., assistant surgeon, is relieved from duty at Fort Columbus, to take effect upon the arrival at that station of Major WM. H. Corbuser, surgeon. He will then report to the commanding officer, detachment of recruits, Fort Shum, to sail on the U. S. transport "Buford," on or about November 1. Upon his arrival at Manila, will report to the commanding general, division of the Philippines, for assignment to duty.

COSTINE, EDWARD F., hospital steward, Fort Columbus, is relieved from further duty in the division of Cuba, and will be sent to Jefferson Barracks for duty.

POINDEXTER, Captain JEFFERSON D., assistant surgeon, will report to the senior member of the board of officers appointed by par. 19, S. O. 295, December 20, 1899, from this office, upon the arrival of that board at Fort Reno, for the purpose of accompany-

ing the command that may be detailed to make a practical test of the emergency ration.

PROBERT, MERTON A., acting assistant surgeon, is relieved from temporary duty at Columbus Barracks, and will proceed to San Francisco, Cal., and report to the commanding general, department of California, for assignment to duty with troops destined for the Philippine Islands.

O'REILLY, PATRICK, hospital steward, now in Washington, D. C., will return to his proper station with permission to delay 30 days en route.

NEWLOVE, GEORGE, acting assistant surgeon, is relieved from duty at Fort Leavenworth, and will proceed to his home, Newcastle, Del., and report by letter to the Surgeon-General of the Army, for annulment of contract.

SALEBY, N. M., acting assistant surgeon, Fort Snelling, will be directed by the post commander to report to the commanding officer, Second Battalion, Eighth Infantry, for duty with that battalion while en route to the Philippine Islands.

BROWN, CLARK L., hospital steward, Fort Snelling, will be directed by the post commander to report to the commanding officer, Second Battalion, Eighth Infantry, for duty with that battalion while en route to the Philippine Islands.

TREHOLTZ, CLARENCE A., acting assistant surgeon, is relieved from temporary duty at the Presidio, and will proceed to camp near Three Rivers, Tulare County, Cal., where he will report to the commanding officer, Troop G, Sixth Cavalry, for duty, to relieve Acting Assistant Surgeon R. C. Stoney.

STONEV, R. C., acting assistant surgeon, will proceed to San Francisco, Cal., for instructions.

KUHN, CHARLES F., acting assistant surgeon, is relieved from temporary duty at the Presidio, and assigned to duty on the transport "Lawton," during the voyage of that vessel to the department of Alaska, and return to San Francisco, Cal.

SHORES, EDWIN I., acting assistant surgeon, now on duty at Fort Caswell, is granted leave for 1 month, from about October 10.

Acting Assistant Surgeons WILLIAM J. CONDON, WILLIAM V. KELLOGG, JAMES C. RUTLEDGE, THOMAS F. MILLER, U. S. GRANT DEATON, LOUIS J. PERKINS, WILLIAM E. CASS and PAUL R. FLETCHER, are relieved from temporary duty at the Army General Hospital, Presidio, and assigned to temporary duty with troops on the transport "Rosecrans," to sail for the Philippine Islands about August 30. Upon arrival in Manila, the medical officers named will report to the commanding general, division of the Philippines, for assignment to duty.

Changes in the U. S. Marine-Hospital Service for the week ended September 13, 1900:

BAILHACHE, PRESTON H., surgeon, granted leave of absence for 9 days from September 14.

IRWIN, FAIRFAX, surgeon, to proceed to Boston quarantine for special temporary duty. September 12.

McINTOSH, W. P., surgeon, to proceed to Biloxi and Ship Island for special temporary duty. September 10.

KINYOUN, J. J., surgeon, to proceed to Victoria, Port Townsend and Astoria quarantine for special temporary duty. September 7.

WERTENBAKER, C. P., passed assistant surgeon, to proceed to Galveston, Tex., for special temporary duty. September 10.

BROWN, B. W., passed assistant surgeon, granted leave of absence for 2 months from November 1.

ANDERSON, J. F., assistant surgeon, to proceed to Liverpool, Eng., for special temporary duty. September 7.

FRANCIS, EDWARD, assistant surgeon, relieved from duty at New York, N. Y. (Stapleton), and directed to proceed to the immigration station and report to Surgeon L. L. Williams for duty. September 10.

BAHRENBURG, L. P. H., assistant surgeon, relieved from duty at the immigration station and directed to proceed to Liverpool, Eng., reporting to Assistant Surgeon J. F. Anderson, at U. S. Consulate for duty. September 10.

BURFORD, R. E. L., acting assistant surgeon, granted leave of absence for 1 month from September 3.

GOMEZ, S., acting assistant surgeon, granted extension of leave of absence for 10 days from September 19.

MONCREAF, J. A., acting assistant surgeon, directed to proceed to Brunswick Quarantine and assume temporary charge of station for 30 days from November 3.

HUME, LEA, sanitary inspector, to proceed to Galveston and report to Surgeon Peckham for special temporary duty. September 13.

RICHARDSON, S. W., hospital steward, granted leave of absence for 20 days from October 1.

ALLEN, C. C., hospital steward, relieved from duty at Delaware Breakwater, and directed to proceed to Mullet Key Detention Camp and report to medical officer in command for duty and assignment to quarters. September 10.

OLSEN, E. T., hospital steward, relieved from duty at Mullet Key Detention Camp and directed to proceed to Washington, D. D., and report at bureau for duty. September 10.

McKAY, MALCOLM, reinstated and appointed senior hospital steward. September 12.

Changes in the Medical Corps of the U. S. Navy, for the week ended September 15, 1900:

CRAWFORD, C. A., assistant surgeon, is detached from the "Eagle," and ordered to the "Dixie."

GATES, M. F., surgeon, is detached from the Naval Hospital, Norfolk, Va., September 12, and ordered to the "Atlanta," September 15.

McCORMICK, A. M. D., passed assistant surgeon, is ordered to the Naval Hospital, Norfolk, Va., for duty, when detached from the "Montgomery."

MORRIS, L., passed assistant surgeon, is detached from the "Baltimore," when put out of commission, and ordered home and to wait orders.

PEARSON, J., pharmacist, is detached from the "Wheeling," and ordered home and to wait orders.

HIGH, W. E. G., assistant surgeon, is detached from the Naval Hospital, Yokohama, and ordered to the "Oregon."

Foreign News and Notes.

GREAT BRITAIN.

An Hospital for Epileptics.—The trustees of the estate of the late Mr. Lewis, of Manchester, are about to spend £100,000 of the money at their disposal in the building and endowment of an hospital for epileptics.

Charitable Bequests.—The late Mr. Richard Eve, of Aldershot, has bequeathed £2,000 to the Cottage Hospital for the Poor, Aldershot, and £500 to the Kidderminster Infirmary, besides numerous donations to masonic and other charities.

Illegal Practises.—About a dozen bodies of newly-born children found in the East-end and in London proper recently are believed to have come from the West-end. It was declared at an inquest on one of these bodies, held in the City Coroner's Court, that the case was one of illegal operation. Among the suspects are 3 medical men who have long been removed from the Medical Register for illegal practices.

Children Poisoned.—About 600 children from the slums, taken by the Bradford Cinderella Club, recently, for a country holiday, wandered into a plantation and ate the seed pods from laburnum trees. Afterwards 20 suffered from narcotic poisoning, and were removed to Bradford Infirmary. Emetics were administered, and most of the children were put right. Two serious cases were detained.

The Professorship of Military Hygiene at Netley.—Major R. Hamill Firth has been appointed to the professorship of Military Hygiene in the Army Medical School, Netley, in place of Colonel J. Lane Nutter, who has resigned the appointment in consequence of having to proceed to South Africa as a member of the Commission of Inquiry as to dysentery and enteric fever.

British Association for the Advancement of Science.—The seventieth meeting of the British Association, which is this year being held at Bradford under the presidency of Sir William Turner, President of the General Medical Council, opened September 5. The number of members' and associates' tickets issued was on that day about 1,600. The retiring president, Sir Michael Foster, is at present in this country.

Women in British Association.—Previous to the opening of the annual meeting of the British Association for the Advancement of Science at Bradford, the motion of Professor Hartop that women should be admitted to membership in the association was discussed. Sir John Evans, former president of the association, was not in favor of the motion, but it was finally decided to admit women, making membership of the general association a precedent to election to membership in the sections.

A Lady Poorhouse Medical Officer.—At a recent meeting of the Dundee Parish Council applications for the post of resident medical officer at Dundee East Poorhouse were submitted. Both came from lady graduates of Edinburgh. After some discussion whether any appointment should be made, Dr. Laura Stewart Sandeman was appointed at a salary of £100 a year. She studied at University College and the Royal Infirmary, Dundee, and on several occasions she acted in the infirmary as one of the assistant house-physicians. Miss Sandeman afterwards studied in the Extramural School of Medicine, Edinburgh, in the Royal Infirmary, Edinburgh, and the Rotunda Hospital, Dublin.

The Jubilee of Owens College.—The issue of a brochure by Professor Hartop, of Owens College, of Manchester, reminds us that the fiftieth anniversary of its foundation will occur next year, it having been established in 1851 by the munificence of Mr. Owens, a Manchester merchant, whose benevolence was largely supplemented by Mr. Falkener, also a Manchester merchant. For the first 8 years it was a dismal failure, the number of students having fallen off from 62 to 40. From 1860 the college has never looked back, and its student *clientèle* now numbers nearly 1,000. It began with an endowment of about £90,000, and has now to its credit not much less than a million sterling. It is the first and largest college of the Victoria University, others being at Leeds and Liverpool.—[*Medical Press*.]

Origin of Plague in Glasgow.—All cases seem to arise from the wake of a woman who died from supposed pneumonia. This woman lived in a crowded tenement-house and was the wife of a dock-laborer. On August 25, a child named Malloy died, also from pneumonia, and later the mother and two brothers were taken to the hospital, and one of the brothers died, and his death has been certified by the health authorities as having been due to bubonic plague. Mrs. Malloy had attended the wake above spoken of. The Malloy boy is the only death that has so far been certified as due to plague, although it is probable that the two cases of pneumonia were really pneumonic plague. From the organs of the Malloy boy the plague-bacillus has been cultivated. There is no history of any unusual death among rats, although inquiries are on foot and the authorities have rat-catchers out. The infected locality is some little distance removed from the shipping, and the connection between the first case and any infected ship cannot be traced, although, as stated above, the husband of the first suspected case of pneumonia was a dock-laborer. The cases now in hospital, we are informed, are all of the bubonic form, which may account for the small number of deaths. Five more cases have been reported, making a total of 21 cases. In addition, there is one suspect and 115 persons under observation.

CONTINENTAL EUROPE.

University of Utrecht.—Dr. Th. Ziehen, of Jena, has been appointed professor of psychiatry.

A Scandinavian Medical Conference was recently held in Copenhagen. It is said to have been largely attended by physicians from Sweden, Norway, Denmark, and Finland, and to have been a very successful gathering.

Sailors Accidentally Poisoned.—At Marseilles 4 deaths from accidental poisoning occurred recently. A sailor bought what he supposed to be gentian root and made a drink with it, which he served out to all the ship's company, and they were immediately taken ill. It turned out that some other root of a strongly irritant nature had been substituted by mistake, but the nature of the substitution has not yet been ascertained.

Bare Feet as Plague Carriers.—According to the *British Medical Journal*, the Sanitary Council of Constantinople has enjoined all persons to wear shoes or other covering for their feet. The reason assigned for this ordinance is that if persons who go barefoot happen to have scratches or excoriations on these extremities, they may thereby become infected with plague, and so transmit the disease. It takes a good deal to awaken the sanitary conscience of the Sublime Porte, but when it is aroused, its activity would appear to be remarkable.

The exhibit of the Trans-Siberian Railroad at Paris, says an exchange, is attracting much attention, as comfort and hygiene have both been studied in the trains. The walls are smooth wood or tiles; the seats are covered with real or artificial leather; there are shower baths; appliances for cooling the air; gymnastic apparatus; cigar lighters; boiled water in the coolers, and a sanitary official on each train who is a trained nurse and barber. The draperies are reduced to a minimum, and an automatic perfume is set in action as the door of the water-closet is closed.—[*Medical Age*.]

MISCELLANY.

Cholera in Afghanistan.—Cholera is reported by the Russian Consul at Meshed to be assuming alarming proportions in Afghanistan. He urges the establishment of a sanitary cordon on the frontier.

Women May Practise Medicine in Austria.—An imperial decree has been issued in Austria which admits women to practice as physicians and chemists on the same conditions as men.

Hospital Car.—The Prussian department of railways has added to its rolling stock a number of hospital cars, which can be hired in advance for any journey by rail. The cars are fitted with spring-bedstretches, invalids' chairs, and all necessary sanitary equipment.

Foreign Universities.—Dr. Max Nitze, of Berlin, has been promoted to an extraordinary professorship of diseases of the urinary organs.—Dr. Wilhelm Autenrieth has been promoted to an extraordinary professorship of chemistry at Freiburg.—Dr. Bodin, of Rennes, has been appointed professor of pathologic anatomy and bacteriology.

Obituary.—JOHN TRESSILIAN TOLL, of Adelaide, Australia, aged 48.—JOHN ORTON, of Beeston, Notts, August 19, aged 55.—WILHELM WAGNER, of Königshütte.—DR. PORSON, of Nantes.—JAMES MUDGE, of Hayle, Cornwall, August 26.—WILLIAM MARSHALL, of Dumfries, August 30, aged 80.—THOMAS MARTYN SIBBALD, R. N., at Taku, China.—WILLIAM HENRY LOWE, of Woodcote, Wimbledon Park, August 26, aged 85.

Wanted: Head House-Servant and Doctor.—Under the above heading the *Indian Medical Record* quotes the advertisement of "Nawab Syed Delawar Reza," who wants a European, Eurasian, or Armenian "smart doctor" to act as private physician, secretary and steward at 100 rupees monthly, board and lodging. He specifies in conclusion that those not of noble birth need not apply. We fear he has not been overrun with applicants.

Plague in India.—The plague-deaths for the whole of India show a rise, the latest weekly report showing a total of 285. Private information is to the effect that plague is much more prevalent in some places than is reported. The continuance of plague in Calcutta, with from 50 to 100 deaths every week, is very serious. The general mortality of this city is 7 per 1,000 per annum above the normal, and the excess is not entirely accounted for by the plague. In the absence of any other explanation, it is probable that there are more plague-deaths than come to the notice of the authorities. Cholera exists not only in Bombay, but in Madras and in the city of Nagur. Owing to plague existing at Hong-Kong, all officers, men, and camp-followers proceeding to China have had the option of being inoculated with Haffkine's fluid before leaving their stations.

Fear of Bacilli and Its Results.—A few months ago, a doctor arrived in Melbourne, Australia, from India, bringing with him some bubonic germs cultivated in gelatin. The fact leaked out, the health-officers declared the germs constituted a grave public danger, but were at a loss how to deal with them; in framing the protectionist tariff, a short-sighted Parliament had omitted all mention of plague-bacilli. At length, the Customs Department came to the rescue. Gelatin was liable to duty, therefore this particular gelatin had been smuggled, and could legally be confiscated. It was burned, germs and all, and Melbourne breathed freely again. "You will want these cultures for serum some day," said the aggrieved doctor, and his words came true, for not long afterward, when the plague arrived, serum was wanted for purposes of inoculation. All Melbourne could do was to cable and wait for supplies, and regret those cremated germs.

The South African Hospitals Inquiry.—It is gratifying to notice that there is a decided preponderance of testimony in favor of the good work done by the Army Medical Corps in South Africa. Several of the colonial soldiers spoke very emphatically of their personal experience in this respect, and as their testimony was perfectly spon-

taneous and they knew what they were talking about it was reliable and valuable. They freely acknowledged that whatever shortcomings there might have been were of a temporary nature and simply unavoidable and attributable to the strain and stress of war. The testimony of soldiers who have passed through the hospitals in South Africa is the best test that can be applied and it is almost uniformly favorable; and where it is not their criticism is usually perfectly fair, temperate, and just. With regard to the overcrowding of army hospitals people seem to forget that this is occasionally unavoidable. A military hospital, unlike a civil one, is bound to take in and provide for sick and wounded soldiers after an action or outbreak of epidemic disease.

Anticholera Inoculation in India.—Cholera has always been exceedingly virulent and fatal among Coolies employed by tea-planters, especially those who labor on shipboard. At first, they would not submit to treatment, but the advantages of inoculation have become so apparent that they now seek it of their own accord, and the tea-planters are inserting special clauses in their contracts, calling for inoculated Coolies in preference to any others. In some of the tea-districts, in which the mortality used to be very high, cholera has practically been exterminated. Notes on a series of experiments, carried on in Calcutta, show that the results, considered as a whole, were as follows: 654 uninoculated, 71 deaths; 402 inoculated, 12 deaths. Proportion, 3.63 to 1; reduction of mortality by 72.47%.

Pasteur Institute for India.—The Pasteur Institute has been opened at Kasauli for the treatment of persons bitten by rabid animals. The director of the institute is Major D. Semple, who was assistant professor of hygiene at Netley for several years, and has been trained in bacteriology and studied the antirabic treatment in Paris. The treatment itself at Kasauli will be entirely gratuitous, but as it does not involve detention in hospital patients will have to make their own arrangements for board and lodging. Excellent accommodation for all classes can be found at this station. Soldiers bitten by rabid animals will no longer require to be sent from India to Paris for treatment. Major Semple has already had 8 men of the South Staffordshire regiment sent for treatment from Subathu, and applications for admission have been made in the case of sepoys and other natives from various parts of the Punjab and the northwest provinces.—[*Lancet*.]

Practice in China.—Dr. Johnson, a well-known medical missionary, tells some curious and interesting things about practice among the Chinese. He says they are very trying patients and make a strong demand on any doctor's Christian forbearance. To begin with, no Chinaman can be trusted to tell the truth about the history of his case; he simply will not follow directions and, if possible, he will upset the treatment by eating all sorts of things on the sly—such delicacies as green peanuts, pickled pig's stomach, decayed fish roes, raw turnips and Chinese pears, which are hard as a rock and about as nutritious as sawdust. Our mission hospitals made the mistake at the outset of treating everybody gratuitously, and the consequence was that they were overrun with people who were able to pay and who had no sympathy whatever with the cause. At present the mission hospitals have a fixed schedule of charges, ranging from 5 "cash," or about a quarter of a cent, for a quinin powder, to 2000 cash for a minor surgical case. The bona fide paupers, of course, are treated free. One of the large hospitals, at Chee Foo, tried the experiment of posting a notice that patients would be expected to deposit whatever they were able to give in a box fastened to the front gate, and a charitable German visitor started the thing off by putting in £5. During the first month over 900 cases were treated, indoors in clinic, and the box was then opened. It was as empty as a drum. Even the £5 had disappeared. After that the fee system was introduced. The missionary doctors are occasionally called in by the wealthy classes, and generally charge a good, round fee for such service. I was sent for last spring to prescribe for the mother of a rich magistrate, and was informed that I would have to feel her pulse by means of a silk cord extending out from the bedroom. I went through the solemn farce and charged £20 "for style." Subsequently I saw my patient face to face.

Society Report.

CANADIAN MEDICAL ASSOCIATION.

Thirty-third Annual Meeting. Held at Ottawa, September 12, 13, and 14.

[Specially reported for THE PHILADELPHIA [MEDICAL JOURNAL.]

THE "century" meeting, which was the thirty-third annual meeting of the Canadian Medical Association, took place in the Academic Hall of the Ottawa University, Ottawa, on September 12, 13, and 14, Dr. R. W. Powell, the president in the chair, and Dr. F. N. G. Starr, of Toronto, secretary.

The Present Status of the Eliminative and Antiseptic Treatment of Typhoid Fever.—DR. W. B. THISTLE, of Toronto University, read this paper. Some seven years ago he introduced this plan of treatment of typhoid fever to the profession. He claimed that this form of treatment for typhoid fever had time and again been misrepresented by Professor Osler and others, as he had never held to the opinion that the eliminative and antiseptic plan could rid such organs as the liver and spleen of the bacilli lodged in them. When once the typhoid-bacilli gain access to the intestinal tract, the multiplication of them occurs with extreme rapidity and the intestinal contents teem with countless numbers of them. These are not confined to the intestine, but are to be found in the walls and, in fact, in almost every organ of the body. He was of the opinion that the draining of the intestinal walls following upon the action of a purgative, either as calomel or maganese sulphate, would tend to get rid of some of these bacilli in the intestinal walls, but he did not claim that it would effect their exit from the liver, etc. He thought the treatment had been imperfectly applied, in many instances without a clear conception of the underlying principles. Under this plan of treatment Dr. Thistle has never had a single case of hemorrhage, what hemorrhage occurred having been always very slight. He has also had very few perforations,—and 20% of the death-rate is from perforation and hemorrhage. In Toronto this plan of treatment is universally adopted. Statistics at the Toronto General Hospital show that from 1893 up to the present time there have been 833 cases in that institution, with 56 deaths, a mortality of 6½%.

In discussing this paper Dr. MCPHEDRAN said that he had been watching Dr. Thistle's work in this direction from the time of the appearance of his first paper on the subject, but could not agree with all his conclusions. He did not think that this plan of treatment lessened diarrhea, tympanites, fever, nor delirium. He considered that Dr. Thistle was harboring the idea that purgatives in typhoid were a new discovery with him; this was not so. Twenty-five years ago he (Dr. McPhedran) gave these for the first ten days at least. In addition to this he used to give carbohic acid and iodine, and in a certain class of cases he thought he had the exact treatment. Another class would then come along in which that treatment had no effect whatever. He considered that the general toxemia that existed could not be eliminated through the bowel. It had to be done through the kidneys and skin. DR. THISTLE, in his reply, emphasized the fact that he was *not* trying to eliminate bacilli from the glands; in clearing out the bowels, he is trying to eliminate toxins from the body and not bacilli.

A Case of Sarcoma of the Right Nasal Fossa with Acute Sinusitis and Orbital Cellulitis.—DR. PERRY G. GOLDSMITH, Belleville, Ont., presented this paper and patient. The patient was a man of 38 years, a farmer, with an unimportant family and personal history. He consulted the doctor on the fourth of August last with severe frontal headache and double vision. Examination of the nasal fossae revealed growths which, along with some of the bone in the right fossa, were removed. After this, swelling and pain in the eye began, so that it was seen to project far forwards, downwards and outwards. The right nasal fossa was curetted, the tissues being sent to Professor Anderson, of the Trinity Pathological Laboratory at Toronto, who pronounced them of sarcomatous origin, small round-cell variety, with the walls of the bloodvessels thin and poorly developed. The

discharge from the nostril was of an odor similar to that emanating from cancer of the rectum. Up to 10 years ago Bosworth has collected 40 of these cases.

DR. R. A. REEVE stated that a number of years ago he had presented a paper before this Association on the same subject. He directed attention to the importance of examining the nasopharynx in diseases of the orbit. He instanced a similar case to Dr. Goldsmith's. In his case there was little pain, but an examination of the nose revealed the tumor.

President's Address.—On the afternoon of the second day, with a packed hall for an audience, DR. POWELL delivered the annual presidential address. He first recited a few reminiscences when on former occasions the Canadian Medical Association had convened in the Capital City—that was in 1871, 1881, 1889, and 1893. He made reference to the South African War in order to show the unsatisfactory condition of affairs which permitted other colonial surgeons from Australia and New Zealand practising their profession in that land without hindrance, whilst Canadians were debarred from the same privileges. An earnest and united effort on the part of the profession throughout the whole Dominion of Canada in an endeavor to bring about interprovincial registration, would facilitate matters in the direction of securing these privileges for the Canadian profession in other parts of the British Empire. The hackneyed subject of tuberculosis was lightly touched upon, whilst a very important matter relating to the profession, that of a Medical Defence Association, was dealt with at considerable length. Dr. Powell favored the formation of such an association, and later on in the proceedings nominated a committee to look into the question to report on the advisability and practicability of forming a Dominion Association of this character.

Some of My Experiences in the South African War.—DR. GEORGE S. RYERSON addressed the Association on this subject. He dealt first with the experience gained of modern bullets. The very latest returns show that 986 officers and 11,701 non-commissioned officers and men had been wounded, of whom only 733 have died of wounds received in battle, which is to be ascribed to the septic character of the bullet and the prompt attention and antiseptic treatment. Dr. Ryerson then dealt with the wounds caused by these bullets. Referring to poisoned bullets being used; this was not the truth, as the tarnish or verdigris probably accumulated in transit through the barrel. He also doubted the fact of explosive bullets being used. The Boers made use of thousands of Martini-Henry, a heavy bullet, which caused great destruction of soft parts, necessitating amputation. There were few amputations in this war. He quoted Kendal Franks, who had performed 20 amputations in 2,000 cases. While abdominal section in wounds of the abdomen was mainly inadvisable, he saw one case in which the results were excellent. He spoke highly of the magnificent work of the B. A. H. C. DR. T. G. RODDICK, H.P., told of the great sacrifices of Dr. Ryerson in proceeding to South Africa at his own expense to carry out the work of the Red Cross Association. While in England, recently, he stated he had made it his special business to inquire of returning Canadian soldiers as to the hospital management in South Africa, and although he had spoken to many of these, he had failed completely to find a single Canadian who had anything but praise for the hospital arrangements in that country.

Our Race and Consumption.—This was the title of a very able paper contributed by SIR JAMES GRANT, of Ottawa, who considered it an important fact and one worthy of consideration, that races had been born on this continent, had lived and entirely disappeared, leaving mounds in the West, and other traces in Florida and elsewhere, of their undoubted existence, and that thus far there was no information as to the exact cause of the disappearance of these races. He thought it remained for the Anglo-Saxons to see whether they will prove more successful than their predecessors in establishing themselves on this continent. He referred to the loss of 3,000 lives in the fair Province of Ontario in 1893 by consumption alone, and deplored the fact that the people were not as yet alive to their danger. Sir James endorsed the legislation passed at the last session of the provincial parliament designed for the purpose of assisting municipalities in the erection and maintenance of sanatoriums for consumptives.

Recognition and Management of Tuberc Dorsalis.—DR. ALLAN McLANE HAMILTON prepared this paper,

but on account of illness was unable to be present to read it. The president undertook this task. It appeared that, as an etiological factor, syphilis was not referred to by the early writers on this disease. While some would attempt to divide the symptoms of the disease into the leg and eye types, the writer would consider that to be unwarranted. He considered there was a close resemblance, or rather relationship, between the different forms of cerebrospinal sclerosis. There was no disease of the nervous system which had drawn forth so many plans of treatment, and but little or no good had resulted from any one thing. Most tabetics are favorable subjects for expectant treatment, and many derive temporary benefit from some new drug. Looking back over a number of years, he finds that most good has been accomplished where little or no medicine had been given. He has found rest by suspension and persistent cauterization of the back, good treatment. In the opinion of the writer, syphilis cannot be traced in more than 50% of the cases. For the arthropathies of the joints, there is little to be done. Perforating ulcer is a rare feature of locomotor ataxia, and most obstinately resists treatment. He has seen 3 cases of this unusual condition in ataxias, and the ulcer rarely exceeds 2 or 3 cm. in diameter. One authority mentions 5 cases, cured by means of nerve-stretching. Throughout the course of the paper, numerous cases were cited, with their symptoms and treatment.

The Physician's "Vaster Empire."—In this paper, DR. JOHN HUNTER, of Toronto, its contributor, dealt with the questions of sanitary science, education, social purity, and medical missions. Referring to sanitary science, he entered a plea for the broader and freer application of the principles of this branch of medicine, in the building and construction of our homes, schools, churches, theaters, etc. No dwelling-house should be constructed except under the supervision of an architect, and a physician versed in sanitary science. In the matter of sanitary science, architects had improved wonderfully during the past 10 years. Another important question was that of our educational system—the mental and physical health and development of our school children. The best way to secure physical vigor and high mentality was surely within the province of the physician to grapple with and study. In all forms of social purity and impurity, physicians should speak *ex cathedra* against every form of vice and immorality. The boys and the girls of the family should be enlightened as to their sexual proclivities at proper periods by their fathers and mothers, respectively. In medical missions, he referred to the vast field for medical missionary work in foreign countries.

Address in Surgery—Tuberculous Lesions from a Clinical Point of View.—The president introduced MR. EDMUND OWEN in a few well-chosen words. This address was delivered at the evening session of the first day and the distinguished visitor was greeted by a crowded house. In commencing his masterly address, he stated that he would deal with tuberculous lesions as the surgeon meets them day by day in the hospital wards, in private practice, or in the operating theater. Referring to the pathologists, he considered his (the pathologist's) thought to be only of the dead tissue, while the surgeon sees the human tree during its life and rarely follows it after death. The student does clinical and pathological work at different times, and he is enabled to follow the case straight from the ward to the laboratory. He considered that study of the fresh specimen was the best, for the specimen taken from formalin was no more like the condition than canned salmon was like fresh-run fish. He would not hinder experimental research work; it was absolutely necessary. The life of a man was of more value than a sparrow or many guineapigs. It would be almost impossible to overestimate the direct value of the experimental laboratory work. Strumous and scrofulous are now terms devoid of meaning, and we now call tubercle by its proper name. There are three great factors in connection with tuberculosis which the public must be made acquainted with: 1. The disease is communicable; but the public must be allowed a little time before they accept this statement and fact. 2. The disease is preventable; this follows almost as a corollary to the first statement. 3. The disease is curable. Years ago the subject of tuberculosis was regarded as well nigh hopeless, but now we do not consider it of the untractable nature that it was formerly considered. Tuberculous lesions are exactly what they used to be; and Mr. Owen has worked at the

largest children's hospital in London for over a quarter of a century. We now take a much more hopeful view of these lesions. Many of you have studied tuberculous lesions under these skies and also in the mother country. Do you find that the tuberculous lesions are the same in both hemispheres? One rarely hears now of the *vis medicatrix naturæ*; surgery has rendered it superfluous. All have noticed cases of old-standing hip-joint disease where in time the boy actually grows out of his trouble. This may be a popular superstition, but, like most erratic beliefs, it is founded upon a stratum of truth. In children these chronic diseases are always tuberculous. Where chronic abscesses occur, it will not do to open and drain, but they must be scraped out—their unhealthy lining destroyed. In the treatment of these diseases, the learned surgeon stated that he had failed to find any virtue whatever in the employment of iodoform. It is an irritant and a poison, and it is apt to be septic, as germs can grow over it. Mr. Owen condemned the use of complicated apparatus, and also the forcible correction in cases of spinal deformities. He considers that this deformity does not lend itself to operative treatment. There may, perhaps, be a small class of cases where it may eventually be found applicable, as where bone or organized inflammatory deposits press upon the cord, so that the patient has lost movement in the lower extremities. The plaster of paris jacket must be held responsible for much of the deformity of Potts' disease. The proper treatment of these cases is rest in the horizontal position, with plenty of good fresh air and sunlight. At the conclusion of his extremely able and instructive address the thanks of the Association were moved in a complimentary speech by PROFESSOR SHEPHERD, of Montreal, and seconded by PROFESSOR CAMERON, of Toronto, put by the president, unanimously carried amid great enthusiasm, and appropriately presented to Mr. Owen by DR. POWELL. MR. OWEN made a happy reply.

Excision of the Knee-Joint in Tuberculous Disease.—PROFESSOR PRIMROSE, of Toronto University, minutely described Kocher's method of dealing with tuberculous disease of the knee-joint, recited the histories of a few cases in which he had obtained excellent results where this operation had been employed. The steps of the operation were made clear by a blackboard drawing; and at the conclusion of his demonstration, Dr. Primrose was highly complimented by Mr. OWEN for his lucid exposition of his subject.

Some Experiences in the Treatment of Hernias.—At the morning session of the second day Dr. F. J. SHEPHERD, of Montreal, contributed the first paper. Some twenty years ago surgeons began to perform these operations by the open method. Older methods in vogue were touched upon and described; and he instanced one very large hernia which had come under his observation then where the man could not put his trousers on. The methods of operation are almost as numerous as surgeons, but there are certain general principles underlying all operations: (1) The necessity for excision or obliteration of the sac; (2) closure of the canal; (3) union by first intention. Some also hold that alteration in the direction of the canal is necessary. The operation performed by Dr. Shepherd is Bassini's, but with it he is not always successful. He has used all kinds of sutures. Absorbable sutures are the best and if antiseptic they are to be preferred. A suture that will last for three weeks is all that is wanted. He has used chromicized catgut now for some time. Professor Shepherd never washes out the wound and thinks it better to dissect out the sac with the knife than to tear it with the fingers. He never uses a drain. For two years past now, he has used rubber gloves in all his surgical work, abdominal in character, and he considers that he has got better results since beginning their use. In hernia operations the mortality is practically nil. Operations on children are now our most successful cases; formerly they were not advised except in strangulated cases.

DR. LAPHORN SMITH discussed this paper and the cases described, although his experience lay mostly in ventral and umbilical work. In some of these he had seen them so large as to require 20 stitches. During the past two years he has abandoned silk and resorted to catgut, chromicized, which he always prepares himself.

Replying to the criticisms, DR. SHEPHERD stated if there was any oozing in the wound, he would pass a probe in between the edges of the wound to let out the accumulated serum. This way he finds to be quite efficacious, as then

you minimize the chance of the introduction of any germs from without.

A Case of Syphilitic Gummata of the Spinal Cord Successfully Treated by Enormous Doses of Iodid of Potash.—DR. F. W. CAMPBELL, of Montreal, reported the history of this very interesting case. It occurred in a man of highly neurotic temperament who, a short time before the onset of symptoms of a definite character, had suffered from repeated attacks of insomnia of a very aggravated character. When his sickness began, there were noticed retention of urine and loss of power in the lower limbs. Patellar reflex was about normal. The loss of power in the lower limbs was absolute. The pulse varied from 80 to 96; the temperature was never above 99. The stomach remained in fairly good condition all the time. A consultant from New York was brought on and a diagnosis established of tumor of the spinal cord situated about the first lumbar vertebra, which might be sarcomatous or syphilitic. The advice of the consultant was to give 500 grains of iodid of potash per day, commencing with a dram 3 times a day. Dr. Campbell detailed minutely the daily history of the patient whilst getting him under the large dose, and then again whilst it was gradually being withdrawn. The patient is alive today and in good health, having recovered complete control of his lower extremities.

Address in Gynecology.—A very practical address was that delivered by DR. WILLIAM GARDNER, of Montreal, on the mistakes in diagnosing gynecological and obstetric cases. He states we often learn more from our mistakes than we do from our successes. Correct and accurate diagnosis depends mainly upon the sense of touch, which can only be attained by long and patient practice. He referred to the advantages of examining on a plain table instead of on a couch or bed. The patient's rectum should always have been emptied before presenting for examination. As for the bladder, it is best to empty that viscus yourself per catheter when the patient is on the table, as in this way you will be able to notice any discharges, etc. That the physician will have to do this often is quite clear from the fact that there are many women of nervous temperament who would not be able to empty the bladder voluntarily in the physician's office. Another advantage of doing this for yourself is, that you get an uncontaminated specimen for examination. In cases where tension is present in the muscles of the abdomen, if you make a series of circular movements over the lower abdomen, gradually narrowing your circle, you will be able to overcome whatever rigidity there may be present. Dr. Gardner urged caution in the use of the uterine sound. He rather considers it a dangerous instrument, that its use ought to be extremely limited; and holds the opinion that many women have lost their lives through this instrument. Then there is the danger and risk of infecting and injuring the uterine canal. This instrument, the uterine sound, is a great deal too much employed by the general practitioner. Mistakes in diagnosing displacements of the uterine body, he considers the most common. The uterus is a very movable organ and a distended rectum or bladder may cause it to be diagnosed as a retroversion. Then it is important to remember that it may be displaced through acts of coughing, vomiting, etc. In all examinations of the pelvic organs, Dr. Gardner has made it a point to examine the position of the kidneys as well. Referring to examination by the Sim's method, it is necessary to have the patient in the proper position; and if you have not a Sim's speculum, a bent table fork or the finger of the opposite hand, may be used to distend the perineum. Mistakes are often made in the diagnosis of pregnancy; but still the patients are few in whom the diagnosis cannot be made by careful examination of history, signs, etc. Many women are probably inaccurate as to date. Dr. Gardner illustrated his points as he proceeded by reciting cases. One in particular he instanced where he once found a woman in his office on her hands and knees in the throes of a twin pregnancy, which a fellow practitioner had failed to recognize and had tapped the gravid uterus and had drawn a quantity of the liquor amnii. Dr. Gardner referred to the mistakes made by himself as well as by his brother practitioners. The close of the paper referred to an interesting account of mistakes which had occurred in diagnosing extrauterine pregnancy. The Association voted him unanimously a hearty vote of thanks for his exceedingly practical paper.

An Unnoticed Factor in the Production of Abdominal and Pelvic Disturbances in Women.—DR. CLARENCE WEBSTER, of Chicago, contributed an interesting paper with the above title. Symptomatology in women, he said, was often overlooked by the general practitioner. The question of the normal relationship of the abdominal and pelvic contents was dwelt upon and then he proceeded to account for intraabdominal pressure, holding to the view that the pelvic organs as well as the abdominal were to a large extent held in their respective positions by reason of the pressure of the abdominal and pelvic walls. He stated the average specific gravity of the viscera to be a little more than that of water; the liver was 1.5 specific gravity. He maintained that there was no proof that the mesenteries acted as constant supports or were ever meant to be such; and the main factor in sustaining the viscera is the strength of the abdominal wall and pelvic floor. Local weakness of the abdominal wall has been fairly well described under hernia; while general weakness of the abdominal wall has been described as pendulous belly. General weakness in his experience is an exceedingly rare condition. As to the question of etiology, the condition is found in women who have borne children; and so, on examination of the great majority of women, there is found some degree of separation of the recti muscles in the region of the navel. All evidence later on may disappear, but permanent widening remains. The results of all this is unavoidable enteroptosis; and this is generally found in women who have been addicted to the pernicious habit of tight lacing. A very common displacement seen is that of the right kidney. Dr. Webster dwelt upon the diagnostic symptoms of these conditions and then proceeded to describe the operation he performs for their relief. This consists in bringing the edges of the two recti muscles into apposition. He first performed this operation in November, 1898. Since that time he has operated upon 41 cases and the results have been most satisfactory in all. MR. I. H. CAMERON took exception to Dr. Webster using the word "unnoticed" in the title of his paper, as he thought this was not an unknown factor in the production of the conditions mentioned in the paper. DR. W. S. MUIR, of Truro, N. S., asked what effect leaving off the use of the binder after confinements had to do with the production of these conditions. DR. WEBSTER held to the opinion that this had not been noticed except by himself and challenged Mr. Cameron to quote authority otherwise. The absence of the binder in his opinion had not made any special difference.

Address in Medicine.—PROFESSOR F. S. SHATTUCK, of Harvard University, said in opening his address that the advance in knowledge had brought about our relation to things in general. There is noticed a subdivision of labor in every branch of industry. As a consequence, specialization has taken place in the science and art of medicine. In specialization lies the cleavage between medicine and surgery; and nowhere has the line been more closely drawn than in England. Anesthesia greatly enlarged the bounds of surgery. Twenty-five years ago there was not a pure surgeon in America. Bellyache is now a surgical disease. The heart is practically the only viscus which remains the exclusive property of the physician; and he was not so sure that even this organ would soon be attacked and we might hear of suturing of the mitral valves. In this country the general practitioner is clinging to obstetrics for family practice. In some of the larger centers, there is now even a tendency to specialism in obstetrics, where the specialist will preside at the accouchment, and the family practitioner then step in to oversee the attendance throughout the puerperium. Pure gynecology scarcely exists today; and pelvic tinkering is suffering from a rapid decline. The great bulk of major gynecology is nothing more than abdominal surgery, which properly belongs to the general surgeon. Gynecologists should study general surgery and become general surgeons first. The field in medicine is so large that no one man can grasp it all in a lifetime. Other specialties were referred to. The desire on the part of some to escape the hurly-burly of general practice may be a cause in throwing them into special lines; and then there is the fact that special knowledge draws larger fees. Ophthalmologists get more for removing a speck of dust from the eye than the general practitioner. When we have specialists for diseases of the young, why not also have a specialty for the diseases of the old? In

the belief of the distinguished professor from Harvard, specialism had come to stay. The gathering was exceedingly delighted with the deliverance of Dr. Shattuck, and at the close voted him a cordial vote of thanks, to which he made an appropriate reply.

Gastric Hemorrhage.—This paper was read by DR. GEORGE E. ARMSTRONG, of Montreal, who believed there was a fairly well-determined field in which surgical interference may be of use in hemorrhage of the stomach. Hemorrhage occurs in 50% of gastric ulcers and is fatal in 8%. Cases are arranged in two groups, the acute and the chronic. Rodman has reported 31 operations for frequently occurring or chronic hemorrhages, with 6 deaths. Dr. Armstrong has operated 5 times for gastric hemorrhage, one being a chronic case. In one of these the patient was getting along nicely after the operation when she expired suddenly; and on a postmortem examination being made, thrombi were found in the branches of the pulmonary artery.

Some Cases in Stomach Surgery—Gastrotomies, Two Cases; Gastroenterostomies, Two Cases; Pylorotomy.—DR. A. E. GARROW, of Montreal, reported these cases. In one patient operated on, the patient was fed before he left the operating table. Another, a woman of 50 years, who had a persistent hacking cough had gastrostomy performed and was discharged able to feed herself through a tube. In another case, in a man aged 33 years, who had vomiting and blood in the stools, the patient suddenly had acute pain with a pale face. Duodenal perforation was present; and when the abdomen was opened gas escaped from the incision. When discharged on July 24 last, he was feeling well. Six cases were reported.

The Modern Treatment of Retroversion and Prolapse of the Uterus.—DR. A. LAPTHORN SMITH presented an able paper with the above title. It referred to the proper and most successful management of procidentia uteri in elderly women between 70 and 75 years of age—a most pitiable condition. Except for this trouble she may be otherwise in excellent health; the perineum, however, is so relaxed that no pessary will remain in place. Then the majority of these cases have an ulcerated cervix. After confinement the uterus remained large and the pernicious habit of keeping women too long on their backs has a tendency to produce the backward displacement. Dr. Smith feels certain that women who have been relieved of this distressing condition will have little difficulty in persuading others to avail themselves of the treatment. He removed a woman's uterus a few months ago which had been out of her body for 20 years, and the patient now assures him that she feels like a young woman. In correcting this deformity Dr. Smith makes a small incision in the abdomen and performs ventrofixation. After that the vaginal canal is narrowed by a large anterior and posterior colporrhaphy. In selected cases he also amputates the lower half of the organ and then stitches the vagina to the upper half. He considers ventrofixation if properly performed a most reliable means of fastening up the uterus. The operation has given him the most complete satisfaction of any operation he has ever performed, especially when combined with amputation of the cervix and posterior colporrhaphy.

Gasoline as a Surgical Detergent.—A paper that was highly original was contributed by DR. BRUCE L. ROIRDAN, of Toronto, on the use of gasoline as a detergent. With this, dirty, greasy hands of machinists, who are the subjects of injuries in these parts, can be effectively and rapidly cleaned, without the ordinary brush, and soap and water. It is far better for this purpose than any method heretofore devised for cleansing. He now constantly carried a small bottle of this in his surgical bag. A report from DR. WILLIAM GOLDIA, of Toronto, showed its effects upon germs and germ life, a report which would conduce to its employment as indicated. One word of caution was thrown out by Dr. Roirdan in its use; as it is a highly inflammable substance it should not be used in any quantity near an exposed light, and it is painful in the eyes or ears. It is also used in cleansing sutures of accumulated serum, blood, and dressing powder, thus freeing these particles and enabling one to locate the stitches easier and quicker. DR. J. C. MITCHELL, of Inniskillen, Ont., stated that he had tried gasoline recently as a detergent in two very severe threshing-machine accidents, where the parts were all smeared over with oil and grease and dirt, and it was very satisfactory, as he was

able to get perfect cleanliness in a short time, both wounds healing by first intention.

Dilation and Prolapse of the Stomach.—PROFESSOR ALEXANDER MCPHEDRAN, of Toronto University, presented this paper, which dealt principally with prolapse. This condition rarely occurs alone, but is associated with prolapse of other abdominal organs. There is generally present as well some degree of dilation, and the abdomen may be prominent or flat, or even retracted. The case of a man aged 51 years was referred to, a manufacturer, who had been ailing for 2 or 3 years. The stomach was below the umbilicus. He was directed to massage the abdomen very thoroughly and to practise abdominal gymnastics. Through this treatment, combined with dietetics and some strychnin, he has been restored to health, and able to resume business. Another case, that of a woman, aged 35 years, was reported. This woman had been the subject of recurrent attacks of vomiting for 2 years. The symptoms were detailed; massage and abdominal gymnastics ordered with satisfactory results. The different ways of examining the stomach were described, and, in concluding, Dr. McPhedran spoke of the benefits of a change of scene in treating these cases.

Physical Training; Its Range and Usefulness in Therapeutics.—DR. B. E. MACKENZIE, of Toronto, gave a very interesting account of the methods employed by him in correcting deformities in his orthopedic hospital in that city. The paper was illustrated by lithographs showing improvements in spinal deformities after physical training in the direction indicated. The paper embraced the results of his observations for 13 years past, and was ample justification of the benefits derived from gymnastics in the correction of lateral curvature, clubfoot, etc. He had also found physical training valuable in hysteria and chorea, especially the former.

Interprovincial Registration.—DR. T. G. RODDICK, M.P., read the report of the committee having this matter in hand. A new feature to be incorporated in the measure was that of allowing the homeopaths representation on the proposed Dominion Council, as according to the law of Ontario, these had their vested rights in that province, and so must be accorded similar interests in any proposed Dominion Council. These will be allowed 3 representatives, which will be equivalent to the representation from any one province of the Dominion. Their term of office will be 4 years. Homeopathy, however, as such, will not be inserted in the measure, but they will be classified under "any other school of medicine having legal recognition in any of the provinces in Canada," as the British Medical Council would not recognize any such body. Dr. Roddick stated that the Bill would be introduced at the next session, and advised the members of the committee from each province to bestir themselves before their respective provincial parliaments, as these bodies must sanction the measure before it can be finally acted upon by the Dominion Parliament.

Cerebral Abscess.—DR. JAMES STEWART, of Montreal, reported 2 interesting cases of abscess of the brain, situated in the temporo-sphenoidal lobe, and referred to the unusual existing aphasia which was present in both cases, viz., simple inability to name objects. The first case occurred in a young man of 22 years, who had otitis media following an attack of influenza. Some 6 weeks afterwards an abscess formed. The abscess was diagnosed as being confined to this area simply on account of the peculiar aphasia,—the simple inability to give the name of a pen when that object was presented to him. The patient was operated on by Professor Ball, who secured 2 ozs. of pus. Meningitis, however, set in and the patient died. The second case was a girl of 21 or 22 years of age. She had had ear trouble for a great many years, with very severe pain at times. She, too, had difficulty in naming objects, and she could not name any object whatever, finally. She died suddenly a few hours before the operation was to be performed for her relief. On opening the skull at the subsequent postmortem examination 2 abscesses were found, 1 skirting the upper margin of the lobe, and the other situated about the center thereof. In reply to a question of the President whether we were to take this kind of aphasia as a distinct diagnostic symptom of abscess in that region, Professor Stewart stated there is what is called a "naming center," and when this is destroyed that particular form of speech defect is present. The cases were aptly illustrated by a diagram.

Gangrene of the Leg Following Typhoid Fever.

—DR. H. H. CHOWN, Winnipeg, reported two cases of gangrene of the leg following typhoid fever, which had recently come under his observation. In the first case the patient had the classical symptoms of typhoid fever, the spots appearing at the end of the first week and being very numerous. Great pain set in in the calf of the leg, with collapse symptoms, while the limb was cold and bloodless. Cutaneous sensibility was lost over the leg. The third day after the complication set in the part involved included the lower third of the leg on the inner side and the lower half of the outer. Operation was done at junction of upper and middle third of femur. Patient stood the operation well. The temperature before the operation was 102.6; pulse 120. On the following day the temperature was normal and the pulse 110. On the tenth day the flaps were united. There was a rise of temperature a few days later—a relapse, with hypostatic congestion of the lungs. On the fifth day after there was hemorrhage of the bowels. The patient is now a picture of health, weighing 200 pounds. The second was a somewhat similar case in which the blood reacted early and promptly to the Widal test. The gangrene began in the first case on the eleventh day of the disease; in the second on the ninth. Keen reports gangrene on the fourteenth day. The gangrene in the second case extended to the upper and middle third of the leg. The leg was amputated and prompt union took place throughout.

Dr. R. B. NEVITT, of Toronto, discussed these cases and mentioned a similar case coming under his observation during the past summer. Gangrene occurred in his case about the third week of the fever, and the patient was seen about a week or ten days thereafter. Amputation was performed through the middle third of the femur. He also referred to a case of gangrene of the arm following an attack of pneumonia, recently observed by him.

Notes on Atropin.—An interesting paper was that contributed by Dr. R. D. RUDOLF, of Toronto University, which was illustrated by means of a chart showing the action of the drug on animals and the inferences drawn therefrom of its therapeutic uses. He finds that the drug directly stimulates the heart, and thus the blood-pressure is markedly raised. He considered that the maximum single dose as laid down by Witherstine of $\frac{1}{30}$ of a grain, as too large unless used as an antidote; and thinks that we ought never to give more than $\frac{1}{100}$ of a grain of atropin sulfate at one time except in emergencies. He also referred to its action in catarrhal pneumonias of children and its employment before anesthesia, to ward off danger.

The paper was discussed by Dr. A. D. BLACKADER, who congratulated Dr. Rudolf upon it and said that he hoped he would pursue his studies farther upon the same subject to find out the effect it would produce in controlling vomiting after anesthesia. He considered, however, that strychnin and not atropin was the most powerful heart tonic in our possession. He thought that late experiments would throw doubt upon atropin being a direct stimulant to the heart-muscle; and he thought it would be questionable practice to administer a drug when he wanted to stimulate the heart's action that would paralyze nerve endings.

Lantern Slide Demonstration of Skin Diseases.

The demonstration of these cases was conducted by Dr. GEORGE H. FOX, of New York City, and it proved to be one which the members of the Association thoroughly appreciated. The great majority of the skin-lesions shown were of syphilitic origin; and as they appeared on the canvas, Dr. Fox described the histories of the cases. One in particular is remembered from the disfigurement of the woman's face. It was a large mass of excrescences on the nose, which Dr. Fox was to get rid of in the course of two or three months, leaving only a slight superficial scar. He laid down a timely word of caution in treating syphilitic conditions, that when the patient was run down and emaciated, through large doses of mercury or iodid of potash, not to keep on pushing these drugs, but to desist for a time, and in the interval endeavor to build up the patient's strength and general condition. That accomplished, return to the specific treatment, and the results would be found to be more beneficial. At the conclusion of the doctor's demonstration, which will rank as one of the features of the meeting, Dr. Fox was voted a cordial vote of thanks for his instructing work.

Dr. F. J. SHEPHERD showed a very interesting case, a boy

of 16 years who, at the age of 6 sustained a severe cutting injury of the nerves and vessels of the axilla, all the nerves of the brachial plexus below the cords of the brachial plexus being severed completely. At that time, 10 years ago, Dr. Shepherd dissected out each nerve separately and united their respective ends by suture. All did well with the exception of the musculo-spiral with which, as a consequence, the lad exercises very little control over the extensors of the forearm.

The Successful Treatment of Two Important Cases of Disease of the Eyes by the Combined Methods of Mercury and Iodid of Potash Internally and Pilocarpin Hypodermically.—DR. G. H. BURNHAM, of Toronto, reported two cases successfully treated by his combined method. Under this method no such result follows in other plans of treatment, and with this plan a permanent result is got. This treatment has a wide application, whether iodid of potash or mercury or the iodid alone be given internally in suitable cases without satisfactory results; if the pilocarpin be added, good results will always follow.

Mental Sanitation.—The assistant superintendent of the Brookville Asylum for the Insane, Dr. R. W. BRUCE SMITH, contributed a scientific paper with the above title. It was a plea for prophylaxis in insanity, and he thought that much would be accomplished in this direction during the twentieth century. Insanity was on the increase in Canada, and it can be ascribed to the fact that while these unfortunates are well attended when they become insane, the fact that there have been no preventive measures employed speaks for itself. In order to accomplish good in this direction, we must seek either to lessen the demands on, or to strengthen the resisting power of, the brain. He condemned intermarriages in families and also amongst those of a deranged mentality. Fifty per cent. of the cases of insanity were hereditary, and the descendants of these should be careful in contracting marriage ties. He referred to a portion of one county in Ontario alone, where indiscriminate marriage and intermarriage has become most fruitful; and he has seen several members of one family from that locality inmates of the same institution at the same time. He considers that the day may yet dawn when we will give the same attention to the rearing of children as we now give to the breeding of horses. Speaking of farm life and the tendency it has to melancholy, he thought this class of the community should receive education in participating more in the enjoyments of life and not to continue to rot in domesticity. An upheaval in the sentiment and surroundings of the rural homes would work wonders in prophylactic principles.

The Canadian Medical Association endorsed the scheme for the formation of a Dominion Anti-Consumptive League. The following were recommended as provisional officers: President (Honorary), the Governor-General. President, Sir James Grant, Ottawa; vice-presidents were appointed for all the provinces; the secretaries are to be the secretaries of the different provincial boards of health; secretary-organizer, Rev. Dr. Eby, Toronto; treasurer, J. M. Courtney, Esq.; deputy finance minister, Ottawa.

The Medical Defence Association.—The Association recommended that Dr. V. H. Moore, of Brookville, be the permanent chairman. One member for each province was appointed. This committee will gather information on the subject and bring in a recommendation at the next annual meeting. The treasurer's report showed that 153 members were in attendance and that there was a balance in the treasury of \$240.65.

Election of Officers.—President, H. H. Chown, Winnipeg; vice-presidents, P. E. I., H. B. Johnson, Charlottetown; N. S., A. J. Haiter, Halifax; N. B., T. D. Walker, St. John; Quebec, A. Laphorn Smith, Montreal; Ontario, A. A. Macdonald, Toronto; Manitoba, J. A. Macdonald, Brandon; N. W. T., J. D. Lafferty, Calgary; British Columbia, S. J. Trinstile, Vancouver. Treasurer, H. B. Small, Ottawa; general secretary, F. G. Starr, Toronto.

Next place of meeting, Winnipeg.

Sir William Hingston and Dr. F. W. Campbell, of Montreal, were appointed on the board of governors of the Victorian Order of Nurses, as representatives of the Canadian Medical Association.

1.—Duncan opened the discussion on the treatment of malaria by quinin at the Section of Tropical Diseases of the British Medical Association. He has no doubt but that quinin has a prophylactic action in relation to malaria. The evidence in regard to the value of arsenic as a prophylactic agent against malaria is conflicting, but in the experience of the author it has been of no benefit. Narcotin is not so efficient as quinin as a prophylactic. For the last 3 years, the
